Abstract

We present our semantic textual similarity approach in filtering a noisy web crawled parallel corpus using YiSi—a novel semantic machine translation evaluation metric. The systems mainly based on this supervised approach perform well in the WMT18 Parallel Corpus Filtering shared task (4th place in 100-million-word evaluation, 8th place in 10-million-word evaluation, and 6th place overall, out of 48 submissions). In fact, our best performing system—NRC-yisi-bicov is one of the only four submissions ranked top 10 in both evaluations. Our submitted systems also include some initial filtering steps for scaling down the size of the test corpus and a final redundancy removal step for better semantic and token coverage of the filtered corpus. In this paper, we also describe our unsuccessful attempt in automatically synthesizing a noisy parallel development corpus for tuning the weights to combine different parallelism and fluency features.

1 Introduction

The WMT18 shared task on parallel corpus filtering (Koehn et al., 2018b) challenged teams to find clean sentence pairs from ParaCrawl, a humongous high-recall, low-precision web crawled parallel corpus (Koehn et al., 2018a), for training machine translation (MT) systems. Data cleanliness of parallel corpora for MT systems is affected by a wide range of factors, e.g., the parallelism of the sentence pairs, the fluency of the sentences in the output language, etc. Previous work (Goutte et al., 2012; Simard, 2014) showed that different types of errors in the parallel training data degrade MT quality at different levels. Intuitively, the crosslingual semantic textual similarity of the sentence pairs in the corpora is one of the most important factors affecting the parallelism of the target sentence pairs. Lo et al. (2016) scored crosslingual semantic textual similarity crosslingually, using a semantic MT quality estimation metric with fewer resource requirements, or monolingually, using a pipeline of MT system and semantic MT evaluation metric with better performance. The core of the National Research Council of Canada (NRC) supervised submissions (NRC-yisi-bicov and NRC-yisi) of the parallel corpus filtering shared task were developed in the same philosophy using a new semantic MT evaluation metric, YiSi (Lo, 2018).

The participants of the parallel corpus filtering shared task were given a large set of “clean” German-English monolingual and bilingual training corpora for the WMT18 news translation shared task (except a filtered version of ParaCrawl) and tasked to score the cleanliness of each sentence pair in the “dirty” ParaCrawl corpus. Our supervised submissions used the given parallel data to train an MT system to translate the German side of the dirty corpus into English. The provided version of the dirty ParaCrawl corpus contains raw data crawled from the web with minimal de-duplication processing only, and includes non-parallel, or even non-linguistic data. It contains 104 million German-English sentence pairs, with 1 billion English tokens and 964 million German tokens before punctuation tokenization. A 10-million-word (10M-word) and a 100-million-word (100M-word) corpus sub-selected by the participating cleanliness scoring system were used to train statistical machine translation (SMT) and neural machine translation (NMT) systems. The success of the participating scoring systems was determined by the quality of the MT output from the four MT systems as measured by BLEU (Papineni et al., 2002) on some in-domain and out-of-domain evaluation sets.

In this paper, we describe the efforts in developing our supervised submissions: the initial fil-
tering steps for scaling down the size of the given ParaCrawl dirty corpus, the wide range of features experimented for measuring parallelism, fluency and grammaticality, the failed attempt to combine useful features and the final redundancy removal for improving token coverage of the filtered corpus. Despite the simple single-feature architecture used in the NRC best-performing supervised submission (NRC-yisi-bicov), it performed well in the MT quality evaluation compared to other participants. It ranked 4th in the 100-million-word evaluation, 8th in the 10-million-word evaluation and 6th overall among 48 submissions. It is one of the only four submissions ranked top 10 in both evaluations.

2 System architecture

There are a wide range of factors constituting a good parallel sentence pair for training MT systems. Some of the more important factors for a good general MT system parallel training corpus include:

- High parallelism in the sentence pairs
- High fluency and grammaticality, especially for sentences in the output language
- High token coverage, especially in the input language
- High variety of sentence lengths

The NRC supervised and unsupervised submissions shared the same general skeleton for the system architecture. The systems consisted of: initial filtering to remove obvious noise and to prevent selections constituted of a large collection of short sentences; feature scoring for measuring parallelism, fluency and grammaticality; feature combination (only in the NRC-mono and NRC-mono-bicov submissions); and final redundancy removal (only in the NRC-*-bicov submissions) to improve token coverage.

2.1 Initial filtering

Although the given “dirty” corpus had already been deduplicated, we did an additional de-duplication step in which email and web addresses were replaced with a placeholder token, before deciding which sentences were duplicates. Sentence pairs were filtered out if the pair was seen before or if the input side was exactly the same as the output side. We also observed that many sentences in the corpus, although parallel, were rather similar and uninformative, especially numerical data such as long lists of page numbers or dates. We observed that using measurements that preferred such sentences resulted in comparatively poor MT performance, likely because the MT systems did not get enough varied data. To mitigate this, we ran two additional filtering steps regarding numbers. First, over 50% of the numbers on each side of the sentence pair had to have a match, otherwise it was filtered out as a bad translation. Next, we removed all the numbers and punctuation and, similar to the previous deduplication step, filtered out sentence pairs if their non-number parts had been seen before, or if the non-number input side was exactly the same as the non-number output side.

A common error found in web crawled corpora is sentences that are in the wrong language. We therefore ran the pyCLD2 language detector\(^1\) on each side of the sentence pair and filtered out pairs whose input side was non-German with a confidence score over 0.5, or whose output side was non-English with a confidence score over 0.5.

Our final filtering step was to remove unreasonably long sentences. Another common error in web crawled corpora is that they contain non-linguistic data, such as tables or computer code. We therefore punctuation-tokenized both sides of the sentence pairs and removed the pair if either side was more than 150 tokens.

The above mentioned steps removed obvious and uninteresting noise and significantly scaled down the size of the original ParaCrawl corpus for more resource demanding feature scoring. The corpus was scaled down from 104 million sentence pairs originally to 28 million sentence pairs.

2.2 Feature scoring

We experimented with a large collection of feature models to address the factors for good general MT training data mentioned at the beginning of this section. Below is a selected list of features that performed reasonably well in our internal sanity check.

2.2.1 Parallelism

**YiSi-1: monolingual semantic MT evaluation metric**

We first used the “clean” WMT18 news translation task monolingual and parallel training data (tokenized and lowercased) to train an

\(^1\)https://github.com/aboSamoor/pyclld2
SMT system using Portage (Larkin et al., 2010), a conventional log-linear phrase-based SMT system. The translation model of the SMT system uses IBM4 word alignments (Brown et al., 1993) with grow-diag-final-and phrase extraction heuristics (Koehn et al., 2003). The system has two n-gram language models: a 5-gram mixture language model (LM) trained on the four corpora components using SRILM (Stolcke, 2002), and a pruned 6-gram LM trained on the WMT monolingual English training corpus built using KenLM (Heafield, 2011). The SMT system also includes a hierarchical distortion model, a sparse feature model consisting of the standard sparse features proposed in Hopkins and May (2011) and sparse hierarchical distortion model features proposed in Cherry (2013), and a neural network joint model, or NNJM, with 3 words of target context and 11 words of source context, effectively a 15-gram LM (Vaswani et al., 2013; Devlin et al., 2014). The parameters of the log-linear model were tuned by optimizing BLEU on the development set (newstest2017) using the batch variant of margin infused relaxed algorithm (MIRA) by Cherry and Foster (2012). Decoding uses the cube-pruning algorithm of Huang and Chiang (2007) with a 7-word distortion limit. We then translated the German side of the filtered ParaCrawl into English.

We also used the monolingual English data to train word embeddings using word2vec (Mikolov et al., 2013) for evaluating monolingual lexical semantic similarity.

YiSi is new a semantic MT evaluation metric inspired by MEANT 2.0 (Lo, 2017). YiSi-1 is equivalent to MEANT 2.0-noSRl. It measures the segmental semantic similarity. The segmental semantic precision and recall divide the inverse-document-frequency weighted sum of the n-gram lexical semantic similarity of the MT output and the English sentence of the target pair by the weighted count of n-grams in the MT output and the English sentences, respectively. In this work, we set the n-gram size to two. Precisely, YiSi-1 is computed as follows:

\[
\begin{align*}
q^0_{i,j} &= \text{ARG } j \text{ of aligned frame } i \text{ in MT} \\
q^1_{i,j} &= \text{ARG } j \text{ of aligned frame } i \text{ in REF} \\
w^0_i &= \# \text{tokens filled in aligned frame } i \text{ of MT} \\
w^1_i &= \# \text{tokens filled in aligned frame } i \text{ of REF} \\
w_j &= \text{count (ARG } j \text{ in REF)} \\
w_t &= 0.25 \ast \text{count (predicate in REF)} \\
\text{srl}_p &= \frac{\sum_i w^0_i \times s_p(e_i^t, f_i^t) + \sum_j w^1_j \times s_p(e^t_j, f^t_j)}{w_t + \sum_i w^0_i + \sum_j w^1_j} \\
\text{srl}_r &= \frac{\sum_i w^0_i \times s_r(e_i^t, f_i^t) + \sum_j w^1_j \times s_r(e^t_j, f^t_j)}{w_t + \sum_i w^0_i + \sum_j w^1_j} \\
\text{precision} &= \beta \ast \text{srl}_p + (1 - \beta) \ast s_p(e^t, f^t) \\
\text{recall} &= \beta \ast \text{srl}_r + (1 - \beta) \ast s_r(e^t, f^t)
\end{align*}
\]

YiSi-1.srl measures the semantic similarity with additional frame semantic or semantic role labeling (srl) information. It uses a more principle way to compute the precision and recall of semantic similarity between the translation output and the reference when comparing to MEANT 2.0. Instead of aggregating the precision and recall at the segmental semantic similarity level, YiSi-1.srl precision is the weighted sum of the segmental semantic precision and the frame semantic precision and similarly, for YiSi-1.srl recall. The frame semantic precision is the weighted sum of the frame semantic precision of the semantic role fillers according to the shallow structural structure parsed by the mateplus (Roth and Woodsend, 2014) English semantic parser over the weighted counts of roles and frames according to the shallow semantic structure of the MT output and similarly, for the frame semantic recall. Precisely, YiSi-1.srl is computed as follows:
When we evaluate MT output in practice, YiSi score is a weighted harmonic mean of the precision and recall. However, in this work, we segregated the precision and recall of YiSi into separate features as we planned to let the regression decide suitable weights to combine them. Further details of YiSi are provided in Lo (2018).

**YiSi-2: crosslingual semantic MT evaluation metric** For the crosslingual version of YiSi, YiSi-2, instead of training a German-English MT system, we used the “clean” WMT18 news translation task parallel training data to train bilingual word embeddings using bivec (Luong et al., 2015) for evaluating crosslingual lexical semantic similarity.

Similar to YiSi-1, YiSi-2 precision and recall are the weighted sum of the crosslingual lexical semantic similarity of the sentence pairs over the weighted count of tokens in the German and English sentences respectively. In this work, we set the n-gram size to one.

YiSi-2 srl precision and recall are the weighted sum of the crosslingual lexical semantic similarity according to the shallow semantic structure parsed by mateplus German and English semantic parser over the weighted counts of roles and frames according to the shallow semantic structure of the German and the English sentence, respectively. We also segregated the precision and recall of YiSi-2 and YiSi-2 srl into separate features for the same reason mentioned above.

**Alignment scores** The SMT model trained on the “clean” WMT18 news translation task parallel training data for YiSi score computation include several alignment models as components, from which probabilities \( p(d|e) \) and \( p(e|d) \) were computed. We find the hidden markov model (HMM) alignment models (Vogel et al., 1996) are reliably useful for scoring parallelism of the sentence pairs in the target corpus.

**Perplexity ratio of input sentences and output sentences** The perplexity ratio reflects the different amounts of information contained in each side of the sentence pairs. This is computed by dividing the smaller perplexity score of the two sentences in the target pair by the larger one. Thus, the ratio ranged from 0 to 1, where a larger value represents better parallelism.

Perplexity ratio of the part-of-speech (POS) tags of the input sentences and output sentences Similar to the previous feature, the perplexity ratio of the input and output sentences POS tags is computed by dividing the smaller POS perplexity score of the two sentences in the target pair by the larger one.

**Distance of sentence vectors** Sentence vectors were trained using sent2vec (Pagliardini et al., 2018) on each side of the “clean” parallel WMT18 news translation task parallel training data. Further details on how to compute these features are described in Littell et al. (2018).

**2.2.2 Fluency and grammaticality**

**Perplexity** 6-gram LMs of the input and output languages were built using KenLM (Heafield, 2011) on the WMT18 news translation task German (263 million sentences) and English (303 million sentences) monolingual corpora.

**Perplexity of POS tags** We parsed the German and the English monolingual training data using mateplus and built 6-gram LMs based on the POS tags using KenLM.

**2.3 Feature combination**

**2.3.1 Synthetic noisy data generation**

We used the WMT09-13 test sets (Callison-Burch et al., 2009, 2010, 2011, 2012; Bojar et al., 2013) as the basis of our development set, as we believe that all the test sets in the previous years are clean and highly parallel, as opposed to the “clean” training data where glitches may occur (especially in the Europarl and CommonCrawl corpora). We introduced several types of synthetic errors into the development set as negative examples and assigned scores according to the severity of each error.

We added the output from the best and the worst participating systems in each year as the mostly parallel but less fluent sentence pairs. We also constructed error sentence pairs by offsetting or deleting tokens on either side, or introducing tokens in the wrong language. The target scores of these pairs are proportional to the percentage of tokens offset, deleted or introduced. Lastly, misaligned sentence pairs were added as fluent but non-parallel negative examples. The resulting development set had 11k sentence pairs of positive and synthetic negative examples.

\[
\text{YiSi-1}_{\text{srl}} = \frac{\text{precision} \cdot \text{recall}}{\alpha \cdot \text{precision} + (1 - \alpha) \cdot \text{recall}}
\]
2.3.2 Regression
In order to benefit from multiple features, we first experimented with linear feature combination. Using the scores generated in §2.2 as features, and the data described in the previous section as modeling data, we trained a linear model with L1 regularization. The amount of regularization was set by optimizing a 10-fold cross-validation estimator of the generalization error on the modeling data. On the synthetic data, it turns out that the optimal level of regularization is minimal, suggesting the overfitting is minimal with this amount of data. We also tried building a linear combination of a subset of the most relevant features, selected from the results of the regularized model built on the full set of features (essentially removing features for which combination weights were not significantly different from zero). The linear features combination models yield marginal improvements according to the cross-validation estimator built from the synthetic data. However, there was no gain in precision when evaluated on our small annotated set or in MT quality when training MT system using data sub-selected by the combined model, so we ended up not submitting the combined results.

2.4 Redundancy filtering
Our scoring mechanisms naturally tend to assign higher scores to semantically similar sentences without paying attention to their usefulness for MT. As a result, we observe much redundancy and a somewhat limited vocabulary coverage in the top-ranking sentences, such as numerous perfectly translated dateline. To compensate for this effect, we applied a form of redundancy filtering after scoring sentence pairs: going down the re-ranked corpus, we filtered out any sentence pair that did not contain at least one “new” source-language word bigram, i.e., a pair of consecutive source-language tokens not observed in previous pairs. This had the effect of excluding sentences that were too similar to one another. Because it was applied post-scoring on the re-ranked corpus, it tended to retain higher-scoring sentence pairs.

3 Experiments and results
3.1 Sanity check
We annotated about 300 random sentence pairs from the filtered target corpus, labeling 93 as correct translations and the rest as non-parallel. We did not tune any parameters to this set, since it was small and also doing so would violate the competition guidelines, but used it to sanity check our feature engineering. We computed the precision of each experimented feature by dividing the number of true positives in the top 93 pairs (scored by the feature) by 93.

Table 1 shows the precision of the experimented features. We also include the results from a random scoring baseline and the given hunalign scores (Initial filtering was integrated into both baselines). YiSi-1 precision was the best performing feature with close to 80% true positive rate in its top ranking sentence pairs. In general, we can see that supervised parallelism features achieved over 73% precision. It is expected that the structural semantic options of YiSi were less accurate as standalone features due to the fact the score for a sentence pair would be zero when the shallow semantic parser failed to find a semantic frame on either side. Our original plan was to combine these features with other semantic features and bias the combined scores to prefer longer sentences with

In addition, the results on MT quality confirmed again that our feature combination was not performing as planned. Compared to the systems trained on data subselected by the best feature (YiSi-1 precision bicov), those trained on data subselected by the regression score list had their performance decreased by 0.2-0.5 BLEU on SMT and 1.6 BLEU on NMT.

Systems in which we applied redundancy removal are labeled “bicov”. On the larger (100M words) selections, the redundancy removal had virtually no effect when applied after YiSi scoring. However, on the smaller (10M words) selection, it allowed for substantial BLEU score increases: +1.61 BLEU for SMT systems on average and +2.44 BLEU for NMT systems.

4 Official Results

Table 3 presents the results of the official BLEU scores on seven development and test sets (devtests) in four training conditions, the average scores across the seven devtests for each of the four training conditions, the average scores across all the devtests for the 10M-word and 100M-word training conditions and the average scores across all the test documents and all training conditions. Our best performing supervised submission—NRC-yisi-bicov ranked 4th in the 100M-word evaluation, 8th in the 10M-word evaluation and 6th overall, out of 48 submissions. In fact, it is one of the only four submissions ranked top 10 in all four training conditions.

Our supervised systems perform strongly on the 100M-word conditions with most of the results in the top 10 (among 48 submissions) and very small differences from the highest score of each test set. Similar to the results from our internal MT quality check, the performance differences of our supervised systems on the 100M-word conditions were very small. In other words, the redundancy re-

Compared to other top-ranking submissions, both of our supervised submissions have weaker MT performance in the 10M-word training conditions although still rank above the median system on all test sets. This suggests that our systems are generally good at identifying parallel sentences for the 100M-word training set but relatively weaker at ranking the sentence pairs according to the usefulness-for-MT beyond parallelism. Although the redundancy removal heuristic appeared to play a more significant role in the 10M-word training conditions, the improvements on the official test sets are less substantial than what we observed in our internal experiments. This is potentially due to the differences in architecture between our MT systems and the MT systems built in the official evaluation.

5 Conclusion

In this paper, we presented the NRC supervised submissions (NRC-yisi-bicov and NRC-yisi) to the WMT18 parallel corpus filtering task. The core of the submissions used YiSi – a novel semantic machine translation (MT) evaluation metric to score the semantic textual similarity between the translated German side and the English of the target sentence pair. Despite failing to combine with other fluency or grammaticality oriented features, the YiSi-based system with redundancy removal performed well in the shared task, particularly in the 100M-word evaluation (4th place out of 48 submitted systems). This shows that using an adequacy oriented scoring measure is a reliable method to identify good sentence pairs for training MT systems. At the same time, the slightly worse performance in the 10M-word evaluation (8th place out of 48 submitted systems) also suggests that fluency or grammaticality oriented features are useful for fine-grained ranking of MT training data quality. Thus, future work includes investigating other feature combination methodologies, such as more realistic tuning example generation.
