Introduction

The Fifth Conference on Machine Translation (WMT 2020) took place on Thursday, November 19 and Friday, November 20, 2020 immediately following the 2020 Conference on Empirical Methods in Natural Language Processing (EMNLP 2020).

This is the fifth time WMT has been held as a conference. The first time WMT was held as a conference was at ACL 2016 in Berlin, Germany, the second time at EMNLP 2017 in Copenhagen, Denmark, the third time at EMNLP 2018 in Brussels, Belgium, and the fourth time at ACL 2019 in Florence, Italy. Prior to being a conference, WMT was held 10 times as a workshop. WMT was held for the first time at HLT-NAACL 2006 in New York City, USA. In the following years the Workshop on Statistical Machine Translation was held at ACL 2007 in Prague, Czech Republic, ACL 2008, Columbus, Ohio, USA, EACL 2009 in Athens, Greece, ACL 2010 in Uppsala, Sweden, EMNLP 2011 in Edinburgh, Scotland, NAACL 2012 in Montreal, Canada, ACL 2013 in Sofia, Bulgaria, ACL 2014 in Baltimore, USA, EMNLP 2015 in Lisbon, Portugal.

The focus of our conference is to bring together researchers from the area of machine translation and invite selected research papers to be presented at the conference.

Prior to the conference, in addition to soliciting relevant papers for review and possible presentation, we conducted 11 shared tasks. These consisted of seven translation tasks: Machine Translation of News, Lifelong Learning for Machine Translation, Robust Machine Translation, Similar Language Translation, Unsupervised and Very Low Resource Supervised Translation, Biomedical Translation, and Machine Translation for Chats, and four other tasks: Automatic Post-Editing, Metrics for Machine Translation, and Parallel Corpus Filtering and Alignment for Low-Resource Conditions.

The results of all shared tasks were announced at the conference, and these proceedings also include overview papers for the shared tasks, summarizing the results, as well as providing information about the data used and any procedures that were followed in conducting or scoring the tasks. In addition, there are short papers from each participating team that describe their underlying system in greater detail.

Like in previous years, we have received a far larger number of submissions than we could accept for presentation. WMT 2020 has received 58 full research paper submissions (not counting withdrawn submissions). In total, WMT 2020 featured 19 full research paper oral presentations and 112 shared task poster presentations.

The invited talk entitled "Low-resourcedness Beyond Data" was given by Ignatius Ezeani, Jade Abbott, Julia Kreutzer, Salomon Kabongo, Perez Ogayo, Shamsuddeen Hassan Muhammad, Rubungo Andre Niyongabo, Jamiil Toure Ali, Kathleen Siminyu, Salomey Osei, Wilhelmina Nekoto, Arshath Ramkilowan, Masabata Mokgesi-Selinga, Bonaventure Dossou, Ayodele Olabiyi, Blessing Sibanda, Akinola Oluwole, Vukosi Marivate, and Orevaoghene Ahia.

We would like to thank the members of the Program Committee for their timely reviews. We also would like to thank the participants of the shared task and all the other volunteers who helped with the evaluations.

Loïc Barrault, Ondřej Bojar, Fethi Bougares, Rajen Chatterjee, Marta R. Costa-jussà, Christian Federmann, Mark Fishel, Alexander Fraser, Yvette Graham, Paco Guzman, Barry Haddow, Matthias Huck, Antonio Jimeno Yepes, Philipp Koehn, André Martins, Makoto Morishita, Christof Monz,

Masaaki Nagata, Toshiaki Nakazawa, Matteo Negri, Aurélie Névéol, Mariana Neves, Martin Popel, Matt Post, Marco Turchi, Marcos Zampieri.

Co-Organizers

Organizers:

Loïc Barrault (University of Sheffield)
Ondřej Bojar (Charles University in Prague)
Fethi Bougares (University of Le Mans)
Rajen Chatterjee (Apple)
Marta R. Costa-jussà (Universitat Politècnica de Catalunya)
Christian Federmann (MSR)
Mark Fishel (University of Tartu)
Alexander Fraser (LMU Munich)
Yvette Graham (DCU)
Paco Guzman (Facebook)
Barry Haddow (University of Edinburgh)
Matthias Huck (LMU Munich)
Antonio Jimeno Yepes (IBM Research Australia)
Philipp Koehn (Johns Hopkins University)
André Martins (Unbabel)
Makoto Morishita (NTT)
Christof Monz (University of Amsterdam)
Masaaki Nagata (NTT)
Toshiaki Nakazawa (University of Tokyo)
Matteo Negri (FBK)
Aurélie Névéol (LIMSI, CNRS)
Mariana Neves (German Federal Institute for Risk Assessment)
Martin Popel (Charles University in Prague)
Matt Post (Johns Hopkins University)
Marco Turchi (FBK)
Marcos Zampieri (Rochester Institute of Technology)

Invited Speakers:

Ignatius Ezeani, Jade Abbott, Julia Kreutzer, Salomon Kabongo, Perez Ogayo, Shamsuddeen Hassan Muhammad, Rubungo Andre Niyongabo, Jamiil Toure Ali, Kathleen Siminyu, Salomey Osei, Wilhelmina Nekoto, Arshath Ramkilowan, Masabata Mokgesi-Selinga, Bonaventure Dossou, Ayodele Olabiyi, Blessing Sibanda, Akinola Oluwole, Vukosi Marivate, and Orevaoghene Ahia

Program Committee:

Tamer Alkhouli (AppTek)
Antonios Anastasopoulos (George Mason University)
Yuki Arase (Osaka University)
Mihael Arcan (National Universith of Ireland Galway)
Philip Arthur (Monash University)
Duygu Ataman (University of Zürich)

Eleftherios Avramidis (German Research Center for Artificial Intelligence (DFKI))
Amittai Axelrod (DiDi Labs)
Parnia Bahar (RWTH Aachen University)
Rachel Bawden (University of Edinburgh)
Meriem Beloucif (University of Hamburg)
Chris Brockett (Microsoft Research)
Ozan Caglayan (Imperial College London)
Francisco Casacuberta (Universitat Politècnica de València)
Sheila Castilho (Dublin City University)
Daniel Cer (Google Research; University of California at Berkeley)
Boxing Chen (Alibaba)
Colin Cherry (Google)
Mara Chinea-Rios (Symanto Research)
Vishal Chowdhary (MSR)
Chenhui Chu (Kyoto University)
Josep Crego (SYSTRAN)
James Cross (Facebook)
Raj Dabre (NICT)
Steve DeNeefe (SDL Research)
Michael Denkowski (Amazon)
Mattia A. Di Gangi (AppTek GmbH)
Miguel Domingo (Universitat Politècnica de València)
Kevin Duh (Johns Hopkins University)
Hiroshi Echizen-ya (Hokkai-Gakuen University)
Sergey Edunov (Faceook AI Research)
Miquel Esplà-Gomis (Universitat d'Alacant)
Marcello Federico (Amazon AI)
Yang Feng (Institute of Computing Technology, Chinese Academy of Sciences)
Orhan Firat (Google AI)
Mikel L. Forcada (Universitat d'Alacant)
George Foster (Google)
Atsushi Fujita (National Institute of Information and Communications Technology)
Yang Gao (Institute of Software, Chinese Academy of Sciences)
Ulrich Germann (University of Edinburgh)
Jesús González-Rubio (WebInterpret)
Isao Goto (NHK)
Cyril Goutte (National Research Council Canada)
Roman Grundkiewicz (University of Edinburgh)
Mandy Guo (Google)
Jeremy Gwinnup (Air Force Research Laboratory)
Thanh-Le Ha (Karlsruhe Institute of Technology)
Greg Hanneman (Amazon)
Christian Hardmeier (Uppsala universitet/University of Edinburgh)
John Henderson (MITRE)
Christian Herold (RWTH Aachen University)
Felix Hieber (Amazon)
Almut Silja Hildebrand (Amazon)

Cong Duy Vu Hoang (Oracle)
Mika Hämäläinen (University of Helsinki, Rootroo Ltd)
Kenji Imamura (National Institute of Information and Communications Technology)
Aizhan Imankulova (Tokyo Metropolitan University)
Phillip Keung (Amazon)
Shahram Khadivi (eBay)
Huda Khayrallah (Johns Hopkins University)
Yunsu Kim (RWTH Aachen University)
Rebecca Knowles (National Research Council Canada)
Julia Kreutzer (Google)
Roland Kuhn (National Research Council of Canada)
Shankar Kumar (Google)
Anoop Kunchukuttan (Microsoft AI and Research)
Veronika Laippala (University of Turku)
Surafel Melaku Lakew (Amazon AI)
Ekaterina Lapshinova-Koltunski (Universität des Saarlandes)
Alon Lavie (Unbabel/Carnegie Mellon University)
Jing Li (Department of Computing, The Hong Kong Polytechnic University)
Jindřich Libovický (Ludwig Maximilian University of Munich)
Patrick Littell (National Research Council of Canada)
Fei Liu (University of Central Florida)
Qun Liu (Huawei Noah's Ark Lab)
Samuel Läubli (University of Zurich)
Vivien Macketanz (German Research Center for Artificial Intelligence (DFKI))
Gideon Maillette de Buy Wenniger (Bernoulli Institute for Mathematics, Computer Science and Artificial Intelligence, University of Groningen, Groningen, The Netherlands)
Andreas Maletti (Universität Leipzig)
Sameen Maruf (Monash University)
Arya D. McCarthy (Johns Hopkins University)
Antonio Valerio Miceli Barone (The University of Edinburgh)
Philippe Muller (IRIT, University of Toulouse)
Kenton Murray (Johns Hopkins University)
Tomáš Musil (Charles University)
Mathias Müller (University of Zurich)
Preslav Nakov (Qatar Computing Research Institute, HBKU)
Graham Neubig (Carnegie Mellon University)
Jan Niehues (Maastricht University)
Xing Niu (Amazon AI)
Tsuyoshi Okita (Kyushu institute of technology/RIKEN AIP)
Arturo Oncevay (The University of Edinburgh)
Carla Parra Escartín (Iconic Translation Machines)
Pavel Pecina (Charles University)
Stephan Peitz (Apple)
Sergio Penkale (Lingo24)
Mārcis Pinnis (Tilde)
Maja Popović (ADAPT Centre @ DCU)
Matīss Rikters (The University of Tokyo)

Table of Contents

Conference Program

Thursday, November 19, 2020

9:45–10:00 ***Opening Remarks***

10:00–11:00 **Session 1: Shared Task Overview Papers I (Chair: Rachel Bawden)**

Findings of the 2020 Conference on Machine Translation (WMT20)
Loïc Barrault, Magdalena Biesialska, Ondřej Bojar, Marta R. Costa-jussà, Christian Federmann, Yvette Graham, Roman Grundkiewicz, Barry Haddow, Matthias Huck, Eric Joanis, Tom Kocmi, Philipp Koehn, Chi-kiu Lo, Nikola Ljubešić, Christof Monz, Makoto Morishita, Masaaki Nagata, Toshiaki Nakazawa, Santanu Pal, Matt Post and Marcos Zampieri

Findings of the First Shared Task on Lifelong Learning Machine Translation
Loïc Barrault, Magdalena Biesialska, Marta R. Costa-jussà, Fethi Bougares and Olivier Galibert

Findings of the WMT 2020 Shared Task on Chat Translation
M. Amin Farajian, António V. Lopes, André F. T. Martins, Sameen Maruf and Gholamreza Haffari

Findings of the WMT 2020 Shared Task on Machine Translation Robustness
Lucia Specia, Zhenhao Li, Juan Pino, Vishrav Chaudhary, Francisco Guzmán, Graham Neubig, Nadir Durrani, Yonatan Belinkov, Philipp Koehn, Hassan Sajjad, Paul Michel and Xian Li

11:00–12:30 **Session 2: Shared Task Posters I**

11:00–12:30 **News Translation Task**

11:00–12:30 *The University of Edinburgh's English-Tamil and English-Inuktitut Submissions to the WMT20 News Translation Task*
Rachel Bawden, Alexandra Birch, Radina Dobreva, Arturo Oncevay, Antonio Valerio Miceli Barone and Philip Williams

11:00–12:30 *GTCOM Neural Machine Translation Systems for WMT20*
Chao Bei, Hao Zong, Qingmin Liu and Conghu Yuan

11:00–12:30 *DiDi's Machine Translation System for WMT2020*
Tanfang Chen, Weiwei Wang, Wenyang Wei, Xing Shi, Xiangang Li, Jieping Ye and Kevin Knight

11:00–12:30 *Facebook AI's WMT20 News Translation Task Submission*
Peng-Jen Chen, Ann Lee, Changhan Wang, Naman Goyal, Angela Fan, Mary Williamson and Jiatao Gu

Thursday, November 19, 2020 (continued)

11:00–12:30 *Linguistically Motivated Subwords for English-Tamil Translation: University of Groningen's Submission to WMT-2020*
Prajit Dhar, Arianna Bisazza and Gertjan van Noord

11:00–12:30 *The TALP-UPC System Description for WMT20 News Translation Task: Multilingual Adaptation for Low Resource MT*
Carlos Escolano, Marta R. Costa-jussà and José A. R. Fonollosa

11:00–12:30 *An Iterative Knowledge Transfer NMT System for WMT20 News Translation Task*
Jiwan Kim, Soyoon Park, Sangha Kim and Yoonjung Choi

11:00–12:30 *Tohoku-AIP-NTT at WMT 2020 News Translation Task*
Shun Kiyono, Takumi Ito, Ryuto Konno, Makoto Morishita and Jun Suzuki

11:00–12:30 *NRC Systems for the 2020 Inuktitut-English News Translation Task*
Rebecca Knowles, Darlene Stewart, Samuel Larkin and Patrick Littell

11:00–12:30 *CUNI Submission for the Inuktitut Language in WMT News 2020*
Tom Kocmi

11:00–12:30 *Tilde at WMT 2020: News Task Systems*
Rihards Krišlauks and Mārcis Pinnis

11:00–12:30 *Samsung R&D Institute Poland submission to WMT20 News Translation Task*
Mateusz Krubiński, Marcin Chochowski, Bartłomiej Boczek, Mikołaj Koszowski, Adam Dobrowolski, Marcin Szymański and Paweł Przybysz

11:00–12:30 *Speed-optimized, Compact Student Models that Distill Knowledge from a Larger Teacher Model: the UEDIN-CUNI Submission to the WMT 2020 News Translation Task*
Ulrich Germann, Roman Grundkiewicz, Martin Popel, Radina Dobreva, Nikolay Bogoychev and Kenneth Heafield

11:00–12:30 *The University of Edinburgh's submission to the German-to-English and English-to-German Tracks in the WMT 2020 News Translation and Zero-shot Translation Robustness Tasks*
Ulrich Germann

11:00–12:30 *Contact Relatedness can help improve multilingual NMT: Microsoft STCI-MT @ WMT20*
Vikrant Goyal, Anoop Kunchukuttan, Rahul Kejriwal, Siddharth Jain and Amit Bhagwat

11:00–12:30 *The AFRL WMT20 News Translation Systems*
Jeremy Gwinnup and Tim Anderson

Thursday, November 19, 2020 (continued)

11:00–12:30 *The Ubiqus English-Inuktitut System for WMT20*
François Hernandez and Vincent Nguyen

11:00–12:30 *SJTU-NICT's Supervised and Unsupervised Neural Machine Translation Systems for the WMT20 News Translation Task*
Zuchao Li, Hai Zhao, Rui Wang, Kehai Chen, Masao Utiyama and Eiichiro Sumita

11:00–12:30 *Combination of Neural Machine Translation Systems at WMT20*
Benjamin Marie, Raphael Rubino and Atsushi Fujita

11:00–12:30 *WeChat Neural Machine Translation Systems for WMT20*
Fandong Meng, Jianhao Yan, Yijin Liu, Yuan Gao, Xianfeng Zeng, Qinsong Zeng, Peng Li, Ming Chen, Jie Zhou, Sifan Liu and Hao Zhou

11:00–12:30 *PROMT Systems for WMT 2020 Shared News Translation Task*
Alexander Molchanov

11:00–12:30 *eTranslation's Submissions to the WMT 2020 News Translation Task*
Csaba Oravecz, Katina Bontcheva, László Tihanyi, David Kolovratnik, Bhavani Bhaskar, Adrien Lardilleux, Szymon Klocek and Andreas Eisele

11:00–12:30 *The ADAPT System Description for the WMT20 News Translation Task*
Venkatesh Parthasarathy, Akshai Ramesh, Rejwanul Haque and Andy Way

11:00–12:30 *CUNI English-Czech and English-Polish Systems in WMT20: Robust Document-Level Training*
Martin Popel

11:00–12:30 *Machine Translation for English–Inuktitut with Segmentation, Data Acquisition and Pre-Training*
Christian Roest, Lukas Edman, Gosse Minnema, Kevin Kelly, Jennifer Spenader and Antonio Toral

11:00–12:30 *OPPO's Machine Translation Systems for WMT20*
Tingxun Shi, Shiyu Zhao, Xiaopu Li, Xiaoxue Wang, Qian Zhang, Di Ai, Dawei Dang, Xue Zhengshan and JIE HAO

11:00–12:30 *HW-TSC's Participation in the WMT 2020 News Translation Shared Task*
Daimeng Wei, Hengchao Shang, Zhanglin Wu, Zhengzhe Yu, Liangyou Li, Jiaxin Guo, Minghan Wang, Hao Yang, Lizhi Lei, Ying Qin and Shiliang Sun

11:00–12:30 *IIE's Neural Machine Translation Systems for WMT20*
Xiangpeng Wei, Ping Guo, Yunpeng Li, Xingsheng Zhang, Luxi Xing and Yue Hu

Thursday, November 19, 2020 (continued)

11:00–12:30 *The Volctrans Machine Translation System for WMT20*
Liwei Wu, Xiao Pan, Zehui Lin, Yaoming ZHU, Mingxuan Wang and Lei Li

11:00–12:30 *Tencent Neural Machine Translation Systems for the WMT20 News Translation Task*
Shuangzhi Wu, Xing Wang, Longyue Wang, Fangxu Liu, Jun Xie, Zhaopeng Tu, Shuming Shi and Mu Li

11:00–12:30 *Russian-English Bidirectional Machine Translation System*
ariel Xv

11:00–12:30 *The DeepMind Chinese–English Document Translation System at WMT2020*
Lei Yu, Laurent Sartran, Po-Sen Huang, Wojciech Stokowiec, Domenic Donato, Srivatsan Srinivasan, Alek Andreev, Wang Ling, Sona Mokra, Agustin Dal Lago, Yotam Doron, Susannah Young, Phil Blunsom and Chris Dyer

11:00–12:30 *The NiuTrans Machine Translation Systems for WMT20*
Yuhao Zhang, Ziyang Wang, Runzhe Cao, Binghao Wei, Weiqiao Shan, Shuhan Zhou, Abudurexiti Reheman, Tao Zhou, Xin Zeng, Laohu Wang, Yongyu Mu, Jingnan Zhang, Xiaoqian Liu, Xuanjun Zhou, Yinqiao Li, Bei Li, Tong Xiao and Jingbo Zhu

11:00–12:30 Test Sets

11:00-12:30 *Fine-grained linguistic evaluation for state-of-the-art Machine Translation*
Eleftherios Avramidis, Vivien Macketanz, Ursula Strohriegel, Aljoscha Burchardt and Sebastian Möller

11:00–12:30 *Gender Coreference and Bias Evaluation at WMT 2020*
Tom Kocmi, Tomasz Limisiewicz and Gabriel Stanovsky

11:00–12:30 *The MUCOW word sense disambiguation test suite at WMT 2020*
Yves Scherrer, Alessandro Raganato and Jörg Tiedemann

11:00–12:30 *WMT20 Document-Level Markable Error Exploration*
Vilém Zouhar, Tereza Vojtěchová and Ondřej Bojar

Thursday, November 19, 2020 (continued)

11:00–12:30 Similar Language Translation Task

11:00–12:30 *Translating Similar Languages: Role of Mutual Intelligibility in Multilingual Transformers*
Ife Adebara, El Moatez Billah Nagoudi and Muhammad Abdul Mageed

11:00–12:30 *Attention Transformer Model for Translation of Similar Languages*
Farhan Dhanani and Muhammad Rafi

11:00–12:30 *Transformer-based Neural Machine Translation System for Hindi – Marathi: WMT20 Shared Task*
Amit Kumar, Rupjyoti Baruah, Rajesh Kumar Mundotiya and Anil Kumar Singh

11:00–12:30 *Hindi-Marathi Cross Lingual Model*
Sahinur Rahman Laskar, Abdullah Faiz Ur Rahman Khilji, Partha Pakray and Sivaji Bandyopadhyay

11:00–12:30 *Transfer Learning for Related Languages: Submissions to the WMT20 Similar Language Translation Task*
Lovish Madaan, Soumya Sharma and Parag Singla

11:00–12:30 *The IPN-CIC team system submission for the WMT 2020 similar language task*
Luis A. Menéndez-Salazar, Grigori Sidorov and Marta R. Costa-Jussà

11:00–12:30 *NMT based Similar Language Translation for Hindi - Marathi*
Vandan Mujadia and Dipti Sharma

11:00–12:30 *NUIG-Panlingua-KMI Hindi-Marathi MT Systems for Similar Language Translation Task @ WMT 2020*
Atul Kr. Ojha, Priya Rani, Akanksha Bansal, Bharathi Raja Chakravarthi, Ritesh Kumar and John P. McCrae

11:00–12:30 *Neural Machine Translation for Similar Languages: The Case of Indo-Aryan Languages*
Santanu Pal and Marcos Zampieri

11:00–12:30 *Neural Machine Translation between similar South-Slavic languages*
Maja Popović and Alberto Poncelas

11:00–12:30 *Infosys Machine Translation System for WMT20 Similar Language Translation Task*
Kamalkumar Rathinasamy, Amanpreet Singh, Balaguru Sivasambagupta, Prajna Prasad Neerchal and Vani Sivasankaran

Thursday, November 19, 2020 (continued)

11:00–12:30 *Document Level NMT of Low-Resource Languages with Backtranslation*
Sami Ul Haq, Sadaf Abdul Rauf, Arsalan Shaukat and Abdullah Saeed

11:00–12:30 *Multilingual Neural Machine Translation: Case-study for Catalan, Spanish and Portuguese Romance Languages*
Pere Vergés Boncompte and Marta R. Costa-jussà

11:00–12:30 *A3-108 Machine Translation System for Similar Language Translation Shared Task 2020*
Saumitra Yadav and Manish Shrivastava

11:00–12:30 Chat Translation Task

11:00–12:30 *The University of Maryland's Submissions to the WMT20 Chat Translation Task: Searching for More Data to Adapt Discourse-Aware Neural Machine Translation*
Calvin Bao, Yow-Ting Shiue, Chujun Song, Jie Li and Marine Carpuat

11:00–12:30 *Naver Labs Europe's Participation in the Robustness, Chat, and Biomedical Tasks at WMT 2020*
Alexandre Berard, Ioan Calapodescu, Vassilina Nikoulina and Jerin Philip

11:00–12:30 *The University of Edinburgh-Uppsala University's Submission to the WMT 2020 Chat Translation Task*
Nikita Moghe, Christian Hardmeier and Rachel Bawden

11:00–12:30 *JUST System for WMT20 Chat Translation Task*
Roweida Mohammed, Mahmoud Al-Ayyoub and Malak Abdullah

11:00–12:30 *Tencent AI Lab Machine Translation Systems for WMT20 Chat Translation Task*
Longyue Wang, Zhaopeng Tu, Xing Wang, Li Ding, Liang Ding and Shuming Shi

12:30–13:00 ***Break***

Thursday, November 19, 2020 (continued)

13:00–14:00 Session 3: Research Papers I (Chair: Tom Kocmi)

Combining Sequence Distillation and Transfer Learning for Efficient Low-Resource Neural Machine Translation Models
Raj Dabre and Atsushi Fujita

Fast Interleaved Bidirectional Sequence Generation
Biao Zhang, Ivan Titov and Rico Sennrich

Priming Neural Machine Translation
Minh Quang Pham, Jitao Xu, Josep Crego, François Yvon and Jean Senellart

Subword Segmentation and a Single Bridge Language Affect Zero-Shot Neural Machine Translation
Annette Rios, Mathias Müller and Rico Sennrich

Look It Up: Bilingual and Monolingual Dictionaries Improve Neural Machine Translation
Xing Jie Zhong and David Chiang

14:00–16:00 ***Break***

16:00–17:00 Session 4: Shared Task Overview I (Chair: Antonio Toral)

17:00–18:30 Session 5: Shared Task Posters I

18:30–19:00 ***Break***

Thursday, November 19, 2020 (continued)

19:00–20:00 Session 6: Research Papers II (Chair: Colin Cherry)

Complete Multilingual Neural Machine Translation
Markus Freitag and Orhan Firat

Paraphrase Generation as Zero-Shot Multilingual Translation: Disentangling Semantic Similarity from Lexical and Syntactic Diversity
Brian Thompson and Matt Post

When Does Unsupervised Machine Translation Work?
Kelly Marchisio, Kevin Duh and Philipp Koehn

Language Models not just for Pre-training: Fast Online Neural Noisy Channel Modeling
Shruti Bhosale, Kyra Yee, Sergey Edunov and Michael Auli

Friday, November 20, 2020

9:00–10:00 Session 7: Research Papers III (Chair: Marta R. Costa-jussà)

Towards Multimodal Simultaneous Neural Machine Translation
Aizhan Imankulova, Masahiro Kaneko, Tosho Hirasawa and Mamoru Komachi

Diving Deep into Context-Aware Neural Machine Translation
Jingjing Huo, Christian Herold, Yingbo Gao, Leonard Dahlmann, Shahram Khadivi and Hermann Ney

A Study of Residual Adapters for Multi-Domain Neural Machine Translation
Minh Quang Pham, Josep Maria Crego, François Yvon and Jean Senellart

Mitigating Gender Bias in Machine Translation with Target Gender Annotations
Artūrs Stafanovičs, Mārcis Pinnis and Toms Bergmanis

Document-aligned Japanese-English Conversation Parallel Corpus
Matīss Rikters, Ryokan Ri, Tong Li and Toshiaki Nakazawa

Friday, November 20, 2020 (continued)

10:00–11:00 Session 8: Shared Task Overview Papers II (Chair Jindřich Libovický)

Findings of the WMT 2020 Shared Task on Automatic Post-Editing
Rajen Chatterjee, Markus Freitag, Matteo Negri and Marco Turchi

Findings of the WMT 2020 Biomedical Translation Shared Task: Basque, Italian and Russian as New Additional Languages
Rachel Bawden, Giorgio Maria Di Nunzio, Cristian Grozea, Inigo Jauregi Unanue, Antonio Jimeno Yepes, Nancy Mah, David Martinez, Aurélie Névéol, Mariana Neves, Maite Oronoz, Olatz Perez-de-Viñaspre, Massimo Piccardi, Roland Roller, Amy Siu, Philippe Thomas, Federica Vezzani, Maika Vicente Navarro, Dina Wiemann and Lana Yeganova

Results of the WMT20 Metrics Shared Task
Nitika Mathur, Johnny Wei, Markus Freitag, Qingsong Ma and Ondřej Bojar

Findings of the WMT 2020 Shared Task on Parallel Corpus Filtering and Alignment
Philipp Koehn, Vishrav Chaudhary, Ahmed El-Kishky, Naman Goyal, Peng-Jen Chen and Francisco Guzmán

Findings of the WMT 2020 Shared Task on Quality Estimation
Lucia Specia, Frédéric Blain, Marina Fomicheva, Erick Fonseca, Vishrav Chaudhary, Francisco Guzmán and André F. T. Martins

Findings of the WMT 2020 Shared Tasks in Unsupervised MT and Very Low Resource Supervised MT
Alexander Fraser

11:00–12:30 Session 9: Shared Task Posters II

Automatic Post-Editing Task

11:00–12:30 *Cross-Lingual Transformers for Neural Automatic Post-Editing*
Dongjun Lee

11:00–12:30 *POSTECH-ETRI's Submission to the WMT2020 APE Shared Task: Automatic Post-Editing with Cross-lingual Language Model*
Jihyung Lee, WonKee Lee, Jaehun Shin, Baikjin Jung, Young-Kil Kim and Jong-Hyeok Lee

11:00–12:30 *Noising Scheme for Data Augmentation in Automatic Post-Editing*
WonKee Lee, Jaehun Shin, Baikjin Jung, Jihyung Lee and Jong-Hyeok Lee

11:00–12:30 *Alibaba's Submission for the WMT 2020 APE Shared Task: Improving Automatic Post-Editing with Pre-trained Conditional Cross-Lingual BERT*
Jiayi Wang, Ke Wang, Kai Fan, Yuqi Zhang, Jun Lu, Xin Ge, Yangbin Shi and Yu Zhao

11:00–12:30 *HW-TSC's Participation at WMT 2020 Automatic Post Editing Shared Task*
Hao Yang, Minghan Wang, Daimeng Wei, Hengchao Shang, Jiaxin Guo, Zongyao Li, Lizhi Lei, Ying Qin, Shimin Tao, Shiliang Sun and Yimeng Chen

Biomedical Translation Task

11:00–12:30 *LIMSI @ WMT 2020*
Sadaf Abdul Rauf, José Carlos Rosales Núñez, Minh Quang Pham and François Yvon

11:00–12:30 *Elhuyar submission to the Biomedical Translation Task 2020 on terminology and abstracts translation*
Ander Corral and Xabier Saralegi

11:00–12:30 *YerevaNN's Systems for WMT20 Biomedical Translation Task: The Effect of Fixing Misaligned Sentence Pairs*
Karen Hambardzumyan, Hovhannes Tamoyan and Hrant Khachatrian

11:00–12:30 *Pretrained Language Models and Backtranslation for English-Basque Biomedical Neural Machine Translation*
Inigo Jauregi Unanue and Massimo Piccardi

11:00–12:30 *Lite Training Strategies for Portuguese-English and English-Portuguese Translation*
Alexandre Lopes, Rodrigo Nogueira, Roberto Lotufo and Helio Pedrini

Abstract

This paper presents the results of the news translation task and the similar language translation task, both organised alongside the Conference on Machine Translation (WMT) 2020. In the news task, participants were asked to build machine translation systems for any of 11 language pairs, to be evaluated on test sets consisting mainly of news stories. The task was also opened up to additional test suites to probe specific aspects of translation. In the similar language translation task, participants built machine translation systems for translating between closely related pairs of languages.

1 Introduction

The Fifth Conference on Machine Translation (WMT20)[1] was held online with EMNLP 2020 and hosted a number of shared tasks on various aspects of machine translation. This conference built on 14 previous editions of WMT as workshops and conferences (Koehn and Monz, 2006; Callison-Burch et al., 2007, 2008, 2009, 2010, 2011, 2012; Bojar et al., 2013, 2014, 2015, 2016, 2017, 2018; Barrault et al., 2019).

This year we conducted several official tasks. We report in this paper on the news and similar translation tasks. Additional shared tasks are described in separate papers in these proceedings:

- automatic post-editing (Chatterjee et al., 2020)
- biomedical translation (Bawden et al., 2020b)
- chat translation (Farajian et al., 2020)
- lifelong learning (Barrault et al., 2020)
- metrics (Mathur et al., 2020)
- parallel corpus filtering (Koehn et al., 2020)
- quality estimation (Specia et al., 2020a)
- robustness (Specia et al., 2020b)
- unsupervised and very low-resource translation (Fraser, 2020)

In the news translation task (Section 2), participants were asked to translate a shared test set, optionally restricting themselves to the provided training data ("constrained" condition). We included 22 translation directions this year, with translation between English and each of Chinese, Czech, German and Russian, as well as French to and from German being repeated from last year, and English to and from Inuktitut, Japanese, Polish and Tamil being new for this year. Furthermore, English to and from Khmer and Pashto were included, using the same test sets as in the corpus filtering task. The translation tasks covered a range of language families, and included both low-resource and high-resource pairs. System outputs for each task were evaluated both automatically and manually, but we only include the manual evaluation here.

The human evaluation (Section 3) involves asking human judges to score sentences output by anonymized systems. We obtained large numbers of assessments from researchers who contributed evaluations proportional to the number of tasks they entered. In addition, we used Mechanical Turk to collect further evaluations, as well as a pool of linguists. This year, the official manual evaluation metric is again based on judgments of adequacy on a 100-point scale, a method (known

[1] http://www.statmt.org/wmt20/

Proceedings of the 5th Conference on Machine Translation (WMT), pages 1–55

as "direct assessment") that we explored in the previous years with convincing results in terms of the trade-off between annotation effort and reliable distinctions between systems.

The primary objectives of WMT are to evaluate the state of the art in machine translation, to disseminate common test sets and public training data with published performance numbers, and to refine evaluation and estimation methodologies for machine translation. As before, all of the data, translations, and collected human judgments are publicly available.[2] We hope these datasets serve as a valuable resource for research into data-driven machine translation, automatic evaluation, or prediction of translation quality. News translations are also available for interactive visualization and comparison of differences between systems at http://wmt.ufal.cz/ using MT-ComparEval (Sudarikov et al., 2016).

In order to gain further insight into the performance of individual MT systems, we organized a call for dedicated "test suites", each focusing on some particular aspect of translation quality. A brief overview of the test suites is provided in Section 4.

Following the success of the first Similar Language Translation (SLT) task at WMT 2019 and the interest of the community in this topic (Costa-jussà et al., 2018; Popović et al., 2020), we organize a second iteration of the SLT task at WMT 2020. The goal of the shared task is to evaluate the performance of state-of-the-art MT systems on translating between pairs of closely-related languages from the same language family. SLT 2020 features five pairs of similar languages from three language families: Indo-Aryan (Hindi and Marathi), Romance (Catalan, Spanish, and Portuguese), and South-Slavic (Croatian, Serbian, and Slovene). Translations were evaluated in both directions using three automatic metrics: BLEU, RIBES, and TER. Results and main findings of the SLT shared task are discussed in Section 5.

2 News Translation Task

This recurring WMT task assesses the quality of MT on news domain text. As in the previous year, we included Chinese, Czech, German and Russian (into and out of English) as well as French-German. New language pairs for this year were Inuktitut, Japanese, Polish and Tamil (to and from English). We also included the two language pairs from the corpus filtering task (Pashto→English and Khmer→English), to give participants the opportunity to build and test MT systems using the large noisy corpora released for that task.

2.1 Test Data

As in previous years, the test sets consist (as far as possible) of unseen translations prepared specially for the task. The test sets are publicly released to be used as translation benchmarks in the coming years. Here we describe the production and composition of the test sets.

The test sets differed along several dimensions, which we list in Table 1. The differing aspects of the test sets are as follows:

Domain Most test sets are drawn from the "news" domain, which means the source texts were extracted from online news websites, and the translations were produced specifically for the task. The Pashto→English and Khmer→English test sets were drawn from wikipedia and, as last year, the French↔German test sets concentrated on EU-related news.

Due to limited resources and data available, the Inuktitut↔English test sets contain document- and sentence-aligned data collected from two domains: news and parliamentary. The news data were extracted from the Nunatsiaq News online news website. The parliamentary data were debates from the Nunavut Hansard that are more recent than the training corpus.

Development? For new languages we released a development set, produced in the same way as the test set.

Sentence-split? For some pairs, we did not sentence-split the source texts. In these cases, we extracted the text from the HTML source with paragraph breaks retained, and asked translators to maintain only the paragraph breaks. This was done in order to try to improve the quality of the human translation by allowing the translators more freedom. Some analysis of the paragraph-split pairs is presented in Section 2.1.1.

Directional? For most language pairs the source-side of the test set is the original, and the target-side of the test set is the translation. This is in contrast to the situation up until 2018 when our test sets were constructed from both "source-original" and "target-original" parts. Where a

[2] http://statmt.org/wmt20/results.html

development set is provided, it is a mixture of both "source-original" and "target-original" texts, in order to maximise its size, although the original language is always marked in the sgm file, except for Inuktitut↔English. The consequences of directionality in test sets has been discussed recently in the literature (Freitag et al., 2019; Laubli et al., 2020; Graham et al., 2020), and the conclusion is that it can have an effect on detrimental effect on the accuracy of system evaluation. We use "source-original" parallel sentences wherever possible, on the basis that it is the more realistic scenario for practical MT usage.

Exception: the test sets for the two Inuktitut↔English translation directions contain the same data, without regard to original direction. For most news text in the test and development sets, English was the original language and Inuktitut the translation, while the parliamentary data mixes the two directions.

The origins of the news test documents is shown in Table 5, and the size of the test sets in terms of sentence pairs and words is given in Figure 4. We generally aimed for 1000 sentences for a new language pair, and 2000 sentences for a previously used language pair (since there was no need to create a development set for a previously-used language pair). For test sets where the source was not sentence-split (see below) we aimed for an equivalent to 2000 sentences, but in running words.

In order to improve the consistency and quality of the test set translations, this year we prepared common translator briefs to be sent to each agency we used. We show the translator briefs in Appendix B (for sentence-split sources) and Appendix C (for paragraph-split sources).

2.1.1 Paragraph-split Test Sets

For the language pairs English↔Czech, English↔German and English→Chinese, we provided the translators with paragraph-split texts, instead of sentence-split texts. We did this in order to provide the translators with greater freedom and, hopefully, to improve the quality of the translation. Allowing translators to merge and split sentences removes one of the "translation shifts" identified by Popovic (2019), which can make translations create solely for MT evaluation different from translations produced for other purposes.

We first show some descriptive statistics of the source texts, for Czech, English and German, in Table 2, where we used the Moses sentence splitter (Koehn et al., 2007) to provide sentence boundaries. We can see that the number of sentences per paragraph is much lower for English, where in fact 70% of paragraphs only have single sentence. For Czech and German, the mean sentences per paragraph is quite similar (2.62 vs. 2.52).

The main question though, is whether translators tended to preserve the sentence structure when translating. To determine this, we split both source paragraphs and translations into sentence, and aligned them using hunalign (Varga et al., 2005) with the bitextor dictionaries (Esplà-Gomis, 2009). In Table 4 we show the counts of 1-1 sentence alignments, as well as cases where the translator merged or split neighbouring sentences. Note that these counts are approximate, since they are affected by errors in the automatic splitting and alignment.

Looking through examples of merges and splits, we see that most of them are relatively simple changes, where the translator has merged to clauses into a sentence, or split a sentence to clauses. Examples of such merges and splits are shown in Table 3, where the first and second are simple merges or splits, whereas the third is a rare case of more complex reordering. We leave a detailed analysis of the translators' treatment of paragraph-split data for future work.

2.2 Training Data

As in past years we provided a selection of parallel and monolingual corpora for model training, and development sets to tune system parameters. Participants were permitted to use any of the provided corpora to train systems for any of the language pairs. As well as providing updates on many of the previously released data sets, we included several new data sets, mainly to support the new language pairs. These included Wikimatrix (Schwenk et al., 2019), which was added for all language pairs where it was available. The news commentary and europarl corpora that we have been using since the earliest news task now have "data sheets", describing the data sets in standardised format (Costa-jussà et al., 2020).

For Tamil-English, we additionally included some recently crawled multilingual parallel corpora from Indian government websites (Haddow and Kirefu, 2020; Siripragada et al., 2020), the Tanzil corpus (Tiedemann, 2009), the Pavlick dic-

Table 1: The characteristics of the test sets for the news tasks. We show the domain that the test set was drawn from, whether or not we released a development set this year, whether the texts were sentence-split before translation, and whether the direction of translation was preserved. For "directional" test sets, the entire source side of the test set was originally written in the source language, and then translated to the target language. Non-directional test sets are a mixture of "source-original" and "target-original" texts. Finally, we record whether or not the test set contained the original document boundaries.

Language	Documents	Paragraphs	Sentences	Words	Sentences per Paragraph
Czech	102	659	1725	25874	2.62
English	130	1418	2043	44018	1.44
German	118	777	1958	31030	2.52

Table 2: Descriptive statistics of paragraph-split source texts. To count the sentences, we applied the Moses sentence splitter to the texts.

Als Rückzieher sei das aber nicht zu verstehen: "Ganz Ägypten ist der Tahrirplatz".	But that should not be understood as a withdrawal. "All of Egypt is Tahrir square."
"Ich fühle mich unglaublich geehrt und demütig, neben JLo die Latino-Community zu repräsentieren. Denn diese hat eine unglaubliche Stärke in den USA", teilte Shakira in einem Video mit.	"I feel incredibly honored and humbled to be next to J. Lo, representing the Latino community that is such an important force in the United States," Shakira shared in a video.
Man könne die Unternehmen zwar nicht von der Umsatzsteuer auf Sachspenden befreien, erklärte das Ministerium auf eine Frage der Grünen-Bundestagsfraktion, über die die Zeitungen der Funke-Mediengruppe am Freitag berichteten. Die Händler könnten aber den Marktwert der unverkäuflichen Retouren so niedrig ansetzen, dass sie keine oder nur wenig Umsatzsteuer zahlen müssten.	Although it is impossible to exempt companies from VAT on donations in kind, retailers could set the market value of unsaleable returns so low that they would need to pay no or only very little VAT, the Ministry explained in response to a question from the Greens parliamentary group, as reported in newspapers of the Funke media group on Friday.

Table 3: Examples of translations where the translator has split or merged the sentences. The third example is one of the rare examples of a non-trivial merging of the sentence (i.e. there is merging accompanied by reordering)

tionaries (Pavlick et al., 2014), a corpus[3] produced by the University of Moratuwa, the HindEnCorp

[3] https://github.com/nlpcuom/English-Tamil-Parallel-Corpus

	B	1844	94.2	35	43	0
English→German	A	2017	98.7	9	8	0
	B	1816	88.9	12	203	0

Table 4: How the translators treated sentences when translating the paragraph-split texts. We sentence-split and automatically aligned source and translation. We show the number and percentage of sentences which were translated 1-1, as well as the number of times translators merged or split sentences when translating.

(Kunchukuttan et al., 2018) and English and Tamil wikipedia dumps.

The training corpus for Inuktitut↔English is the recently released Nunavut Hansard Inuktitut–English Parallel Corpus 3.0 (Joanis et al., 2020).

For the Japanese↔English tasks, we added several freely available parallel corpora to the training data. It includes JParaCrawl v2.0 (Morishita et al., 2020), a large web-based parallel corpus, Japanese-English Subtitle Corpus (JESC) (Pryzant et al., 2017), the Kyoto Free Translation Task (KFTT) corpus (Neubig, 2011), constructed from the Kyoto-related Wikipedia articles, and TED Talks (Cettolo et al., 2012).

The monolingual data we provided was similar to last year's, with a 2019 news crawl added to all the news corpora. In addition, we provided versions of the news corpora for Czech, English and German, with both the document and paragraph structure retained. In other words, we did not apply sentence splitting to these corpora, and we retained the document boundaries and text ordering of the originals.

Training, development, and test data for Pashto↔English and Khmer↔English are shared with the Parallel Corpus Filtering Shared Task (Koehn et al., 2020). The training data mostly comes from OPUS (software localization, Tatoeba, Global Voices), the Bible, and special-prepared corpora from TED Talks and the Jehova Witness web site (JW300). The development and test sets were created as part of the Flores initiative (Guzmán et al., 2019) by professional translation of Wikipedia content with careful vetting of the translations. Please refer the to the Parallel Corpus Filtering Shared Task overview paper for details on these corpora.

Some statistics about the training and test materials are given in Figures 1, 2, 3 and 4.

2.3 Submitted Systems

In 2020, we received a total of 153 submissions. The participating institutions are listed in Table 6 and detailed in the rest of this section. Each system did not necessarily appear in all translation tasks. We also included online MT systems (originating from 4 services), which we anonymized as ONLINE-A,B,G,Z.

This year we introduced a new submission tool, OCELoT[4], replacing the matrix that has been used in most previous editions. Using OCELoT gave us more control over the submission and scoring process, for example we were able to limit the number of test submissions by each team, and we also displayed the submissions anonymously to avoid publishing any automatic scores. A screenshot of OCELoT is shown in Figure 5.

For presentation of the results, systems are treated as either *constrained* or *unconstrained*, depending on whether their models were trained only on the provided data. Since we do not know how they were built, the online systems are treated as unconstrained during the automatic and human evaluations.

In the rest of this section, we provide brief details of the submitted systems, for those where the authors provided such details.

2.3.1 AFRL (Gwinnup and Anderson, 2020)

AFRL-SYSCOMB20 is a system combination consisting of two Marian transformer ensembles, one OpenNMT transformer system and a Moses phrase-based system.

AFRL-FINETUNE is an OpenNMT transformer system fine-tuned on newstest2014-2017.

2.3.2 ARIEL XV (Xv, 2020)

ARIEL XV is a Transformer base model trained with the Sockeye sequence modeling toolkit us-

Table 6: Participants in the shared translation task. Not all teams participated in all language pairs. The translations from the online systems were not submitted by their respective companies but were obtained by us, and are therefore anonymized in a fashion consistent with previous years of the workshop.

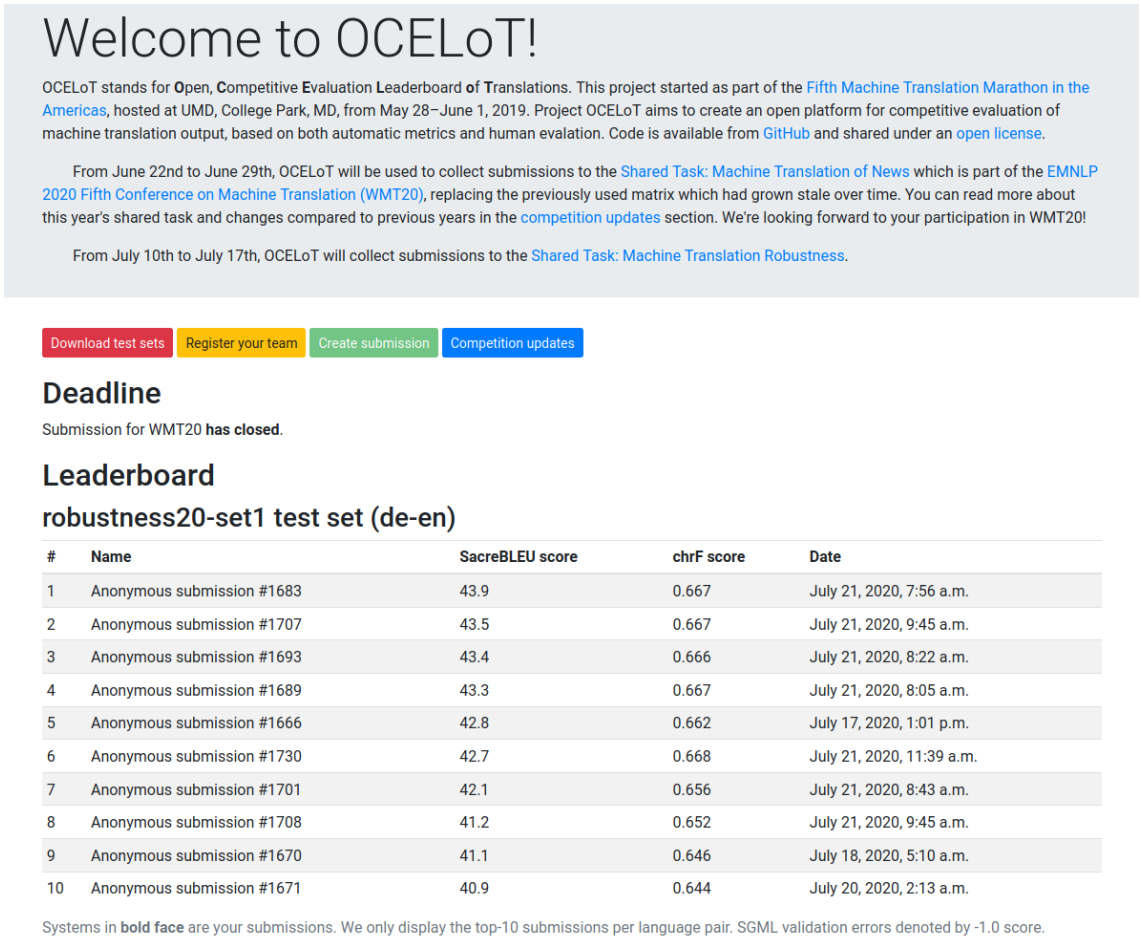

Figure 5: The OCELoT leaderboard tool

ing only the constrained data. The authors experiment with bi-text data filtering, back-translation, rule-based reranking based on translation and language model scores, ensembling several training runs and fine-tuning for sentences similar to the desired domain based on the source side of the test set.

2.3.3 Charles University (CUNI)

CUNI-DocTransformer **(Popel, 2020)** is similar to the sentence-level version (CUNI-T2T-2018, CUBBITT), but trained on sequences with multiple sentences of up to 3000 characters.

CUNI-T2T-2018 **(Popel, 2018),** also called CUBBITT, is exactly the same system as in WMT2018. It is the Transformer model trained according to Popel and Bojar (2018) plus a novel concat-regime backtranslation with checkpoint averaging (Popel et al., 2020), tuned separately for CZ-domain and non CZ-domain articles, possibly handling also translation-direction ("translationese") issues. For cs→en also a coreference preprocessing was used adding the female-gender pronoun where it was pro-dropped in Czech, referring to a human and could not be inferred from a given sentence.

CUNI-Transfer **(Kocmi, 2020)** combines transfer learning from a high-resource language pair Czech–English into the low-resource Inuktitut-English with an additional backtranslation step. Surprising behaviour is noticed when using synthetic data, which can be possibly attributed to a narrow domain of training and test data. The system is the Transformer model in a constrained submission.

CUNI-Transformer **(Popel, 2020)** is similar to the WMT2018 version of CUBBITT, but with 12 encoder layers instead of 6 and trained on CzEng 2.0 instead of CzEng 1.7. The English-Polish version was trained similarly on the provided constrained data.

2.3.4 DCU (Parthasarathy et al., 2020)

DCU participated in the Tamil↔English translations with the Transformer model. Various strate-

gies were tested in order to improve over the baseline, e.g. several techniques of data augmentation and mining as well as a hyperparameter search for better performance of the Transformer model in low-resource scenarios.

2.3.5 DEEPMIND (Yu et al., 2020)

DEEPMIND is a document-level translation system built upon noisy channel factorization. The system optimizes the selection of translations of individual sentences in the document in iterative beam search, replacing sentences with alternative translations. Candidate translations are constructed and later scored using a number of independent components, mainly sequence-to-sequence models trained on large data and highly optimized with techniques of back-translation, distillation, and fine-tuning with in-domain data. MonteCarlo Tree Search decoding and uncertainty estimation are used to improve the robustness of the search for the best sentence translation selection and specialized length models and sentence segmentation help to avoid too short output.

2.3.6 DIDI-NLP (Chen et al., 2020b)

DIDI-NLP is a Transformer model improved with several techniques for model enhancement, including data filtering, data selection, large-scale back-translation, knowledge distillation, fine-tuning, model ensembling, and re-ranking.

Ensembled models include Transformers with relative position attention, larger inner feed-forward network size or reversed source. Multiple domain models based on unsupervised BERT-CLS clusters are used in a dynamically-weighted selection of the next word. The final n-best lists are reranked with MIRA.

2.3.7 DONG-NMT (no associated paper)

No description provided.

2.3.8 ENMT (Kim et al., 2020)

Kim et al. (2020) base their approach on transferring knowledge of domain and linguistic characteristics by pre-training the encoder-decoder model with large amount of in-domain monolingual data through unsupervised and supervised prediction task. The model is then fine-tuned with parallel data and in-domain synthetic data, generated with iterative back-translation. For additional gain, final results are generated with an ensemble model and re-ranked with averaged models and language models.

2.3.9 ETRANSLATION (Oravecz et al., 2020)

ETRANSLATION mainly use the standard training pipeline of Transformer in Marian, using tagged back-translation and other features. Subword units are identified by SentencePiece.

The paper describes the group's concern about computing resources and the practical utility of expensive features like ensembling 2 to 4 bigger models. Techniques that were ineffective in ETRANSLATION's case (e.g. right-to-left model for rescoring English→German or Unicode preprocessing for Japanese→English) are also described.

2.3.10 FACEBOOK AI (Chen et al., 2020a)

FACEBOOK AI focus on low-resource language pairs involving Inuktitut and Tamil using two strategies: (1) exploiting all available data (parallel and monolingual from all languages) and (2) adapting the model to the test domain.

For (1), FACEBOOK AI opt for non-constrained submission, using data derived from CommonCrawl to get strong translation models via iterative backtranslation and self-training and strong language models for noisy channel reranking. Multilingual language models are created using mBART across all the 13 languages of WMT20. For (2), the datasets are tagged for domain, fine-tuned on and further extended with in-domain data.

2.3.11 GRONINGEN

GRONINGEN-ENIU (Roest et al., 2020) investigate the (1) importance of correct morphological segmentation of the polysynthetic Inuktitut, testing rule-based, supervised, semi-supervised as well as unsupervised word segmentation methods, (2) whether or not adding data from a related language (Greenlandic) helps, and (3) whether contextual word embeddings (XLM) improve translation.

GRONINGEN-ENIU use Transformer implemented in Marian with the default setting, improving the performance also with tagged backtranslation, domain-specific data, ensembling and fine-tuning.

GRONINGEN-ENTAM (Dhar et al., 2020) study the effects of various techniques such as linguistically motivated segmentation, back-translation, fine-tuning and word dropout on the English→Tamil News Translation task. Linguis-

tically motivated subword segmentation does not consistently outperform the widely used SentencePiece segmentation despite the agglutinative nature of Tamil morphology. The authors also found that fully-fledged back-translation remains more competitive than its cheaper alternative.

2.3.12 GTCOM (Bei et al., 2020)

GTCOM are unconstrained systems using mBART (Multilingual Bidirectional and Auto-Regressive Transformers), back-translation and forward-translation. Further gains are achieved using rules, language model and RoBERTa model to filter monolingual, parallel sentences and synthetic sentences. The vocabularies are created from both monolingual and parallel data.

2.3.13 HELSINKINLP (Scherrer et al., 2020a)

HELSINKINLP for the Inuktitut-English news translation task focuses on the efficient use of monolingual and related bilingual corpora with multi-task learning as well as an optimized subword segmentation with sampling.

2.3.14 HUAWEI TSC (Wei et al., 2020a)

HUAWEI TSC use Transformer-big with a further increased model size, focussing on standard techniques of careful pre-processing and filtering, back-translation and forward translation, including self-training, i.e. translating one of the sides of the original parallel data. Ensembling of individual training runs is used in the forward as well as backward translation, and single models are created from the ensembles using knowledge distillation. The submission uses THUNMT (Zhang et al., 2017) open-source engine.

2.3.15 IIE (Wei et al., 2020b)

IIE German↔French news translation system is based on the Transformer architecture with some effective improvements. Multiscale collaborative deep architecture, data selection, back translation, knowledge distillation, domain adaptation, model ensemble and re-ranking are employed and proven effective in the experiments.

2.3.16 MICROSOFT STC INDIA (Goyal et al., 2020)

Focusing on English↔Tamil, MICROSOFT STC INDIA experiment with "contact relatedness" of languages, i.e. using Hindi-English data in joint training. Hindi texts first have to be mapped from the Devanagari script to Tamil characters in a lossy but deterministic way. Further gains are obtained from tagged back-translation and other variants of back-translation are also examined (noisification or back-translating with right-to-left models).

Transformer implemented in fairseq is used, with smaller than "base" models due to limited training data.

2.3.17 NICT-KYOTO (Marie et al., 2020)

NICT-KYOTO is a combination of neural machine translation systems processed through n-best list reranking. The systems combined are Transformer-based trained with Marian and Fairseq with and without using tagged back-translation. All the systems are constrained, and the final primary submission is selected on the basis of the BLEU score obtained on the official validation data.

2.3.18 NICT-RUI (Li et al., 2020)

NICT-RUI (Li et al., 2020) NICT-RUI is closely related to SJTU-NICT using large XLM model to improve NMT but the exact relation is unclear.

2.3.19 NIUTRANS (Zhang et al., 2020)

NIUTRANS gain their performance from focussed attention to six areas: (1) careful data preprocessing and filtering, (2) iterative back-translation to generate additional training data, (3) using different model architectures, such as wider and/or deeper models, relative position representation and relative length, to enhance the diversity of translations, (4) iterative knowledge distillation by in-domain monolingual data, (5) iterative fine-tuning for domain adaptation using small training batches, (6) rule-based post-processing of numbers, names and punctuation.

For low-resource language pairs, multi-lingual seed models are used.

2.3.20 NRC (Knowles et al., 2020)

The NRC systems are hybrids of Transformer models trained with Sockeye, with one ensembled system for news domain translation and one for Hansard domain translation. Data was pre-processed with language-specific punctuation and character preprocessing, tokenization, and BPE. They were trained with domain tagging, domain-specific finetuning, ensembles of 3 systems per domain, BPE-dropout (EN-IU), and tagged back-translation (IU-EN).

2.3.21 OPPO (Shi et al., 2020)

OPPO train Marian for some language pairs and fairseq for others, relying on a number of mature techniques including careful corpus filtering, iterative forward and backward translation, fine-tuning on the original parallel data, ensembling of several different models, and complex reranking which uses forward (source-to-target) scorers, backward scorers (target-to-source) and language models (monolingual), each group again building upon ensembles and being applied left-to-right as well as right-to-left.

Each language pair received targeted attention, discussing training data properties, varying the process as needed and choosing from several possible final models.

2.3.22 PROMT (Molchanov, 2020)

PROMT BASELINE TRANSFORMER uses MarianNMT, shared vocabulary, 16k BPE merge operations and it is trained on unconstrained data.

PROMT BASIC TRANSFORMER uses separate vocabs (16k source + 32k target), and tied embeddings.

PROMT MULTILINGUAL 4-TO-EN is a multilingual system trained to translate from Croatian, Serbian, Slovak and Czech to English. It is a basic Transformer configuration with shared vocabulary.

PROMT MULTILINGUAL PL-EN is a Polish↔English system trained jointly in both directions. It uses basic Transformer configuration and shared vocabulary.

None of PROMT systems are constrained.

2.3.23 SJTU-NICT (Li et al., 2020)

SJTU-NICT represents two different main approaches. For News Translation Task, (1) cross-lingual language models (XLM) are used in an additional encoder to benefit from language-independent sentence representations from both the source and target side for Polish→English. For English→Chinese, which includes document-level information, three-stage training is used to train Longformer (Transformer with attention extended to the full document).

2.3.24 SRPOL (Krubiński et al., 2020)

No short description provided.

2.3.25 TALP UPC (Escolano et al., 2020)

No short description provided.

2.3.26 TENCENT TRANSLATION (Wu et al., 2020b)

No short description provided.

2.3.27 THUNLP (no associated paper)

No description provided.

2.3.28 TILDE (Krišlauks and Pinnis, 2020)

For WMT 2020, Tilde developed English↔Polish (separate constrained and unconstrained submissions) and Polish↔English (constrained only) NMT systems. Tilde experimented with morpheme splitting prior to byte-pair encoding, dual conditional cross-entropy filtering, sampling-based backtranslation of source-domain-adherent monolingual data, and right-to-left reranking. The submitted translations were produced using ensembles of Transformer base and Transformer big models, which were trained using back-translated data, and right-to-left re-ranking.

2.3.29 TOHOKU-AIP-NTT (Kiyono et al., 2020)

TOHOKU-AIP-NTT used Transformer-based Encoder-Decoder model with 8 layers and feed forward dimension of 8192. Synthetic data were created via beam back-translation from monolingual data available for each language and incorporated to the training using tagged backtranslation. The bitext was oversampled so that the model saw the bitext and synthetic data in 1:1 ratio. After training, the model was finetuned with newstest corpus.

An ensemble of four models was used to generate candidate translation, which were in turn re-ranked using scores from following components: (1) source-to-target right-to-left model, (2) target-to-source left-to-right model, (3) target-to-source right-to-left model, (4) masked language model (RoBERTa), and (5) uni-directional language model (Transformer-LM).

2.3.30 MULTILINGUAL-UBIQUS (Hernandez and Nguyen, 2020)

UBIQUS performed a single submission, based on an unconstrained multilingual setup. The approach consists of jointly training a traditional Transformer model on several agglutinative languages in order to benefit from them for the low-resource English-Inuktitut task. For that purpose,

the dataset was extended with other linguistically near languages (Finnish, Estonian), as well as in-house datasets introducing more diversity to the domain.

2.3.31 UEDIN

UEDIN **(Bawden et al., 2020a)** for the very low-resource English-Tamil involved exploring pretraining, using both language model objectives and translation using an unrelated high-resource language pair (German-English), and iterative backtranslation. For English-Inuktitut, UEDIN explored the use of multilingual systems.

UEDIN-DEEN **and** UEDIN-ENDE **(Germann, 2020)** ensemble big transformer models trained in three stages: First, base transformer models were trained on available high-quality parallel data. These models were used to rank and select parallel data from crawled and automatically matched parallel data (Paracrawl, Commoncrawl, etc.). 2nd-generation big transformers were then trained on the combined parallel data. These models were used for back-translation. Original and back-translated data was then used to the final 3rd-generation models.

2.3.32 UEDIN-CUNI (Germann et al., 2020)

UEDIN-CUNI CSEN STUDENT **and** UEDIN-CUNI ENCS STUDENT are compact, efficient student models that distill knowledge from larger teacher models. All models are variants of the transformer architecture. The teacher models were used to translate the source side of the training data to create synthetic training data for the student models.

2.3.33 UQAM_TANLE

No description provided.

2.3.34 VOLCTRANS (Wu et al., 2020a)

VOLCTRANS aims at building a general training framework which can be well applied to different translation. directions. Techniques used in the submitted systems include optional multilingual pre-training (mRASP) for low resource languages, very deep Transformer or dynamic convolution models up to 50 encoder layers, iterative back-translation, knowledge distillation, model ensemble and development set fine-tuning. The key ingredient of the process seems the strong focus on diversification of the (synthetic) training data, using multiple scalings of the Transformer model and dynamic convolution, random upsamplings of the parallel data, creation of multiple back-translated corpus variants or random ensembling which uses not a fixed set of ensembled models but rather a random checkpoint of each of them.

2.3.35 WECHAT (Meng et al., 2020)

WECHAT is based on the Transformer with effective variants and the DTMT architecture. The experiments include data selection, several synthetic data generation approaches (i.e., back-translation, knowledge distillation, and iterative in-domain knowledge transfer), advanced finetuning approaches and self-bleu based model ensemble.

2.3.36 WMTBIOMEDBASELINE (Bawden et al., 2020b)

WMTBIOMEDBASELINE are the baseline systems from the Biomedical Translation Task.

2.3.37 YOLO (no associated paper)

No description provided.

2.3.38 ZLABS-NLP

ZLABS-NLP used SentencePiece for subword segmentation, otherwise the model including hyper-parameters is the same as described by Ott et al. (2018) and implemented in FairSeq. Probably, OpenNMT-py was used during training (back-translation for Tamil).

3 Human Evaluation

A human evaluation campaign is run each year to assess translation quality and to determine the official ranking of systems taking part in the news translation task. This section describes how data for the human evaluation is prepared, the process of collecting human assessments, and computation of the official results of the shared task.

3.1 Direct Assessment

Since running a comparison of *direct assessments* (DA, Graham et al., 2013, 2014, 2016) and relative ranking in 2016 (Bojar et al., 2016) and verifying a high correlation of system rankings for the two methods, as well as the advantages of DA, such as quality controlled crowd-sourcing and linear growth relative to numbers of submissions, we have employed DA as the primary mechanism for evaluating systems. With DA human evaluation,

human assessors are asked to rate a given translation by how adequately it expresses the meaning of the corresponding reference translation or source language input on an analogue scale, which corresponds to an underlying absolute 0–100 rating scale.[5] No sentence or document length restriction is applied during manual evaluation. Direct Assessment is also employed for evaluation of video captioning systems at TRECvid (Graham et al., 2018; Awad et al., 2019) and multilingual surface realisation (Mille et al., 2018, 2019).

3.1.1 Source and Reference-based Evaluations

The earlier DA evaluations that we performed were all referenced based, as described above, however in 2018 we trialled source-based evaluation for the first time, in English to Czech translation. In this configuration, the human assessor is shown the source input and system output only (with no reference translation shown). This approach has the advantage of freeing up the human-generated reference translation so that it can be included in the evaluation to provide an estimate of human performance. As was the approach in WMT19, since we would like to restrict human assessors to only evaluate translation *into* their native language, we again restrict bilingual/source-based evaluation to evaluation of translation for out-of-English language pairs. This is especially relevant since we have a large group of volunteer human assessors with native language fluency in non-English languages and high fluency in English, while we generally lack the reverse, i.e. native English speakers with high fluency in non-English languages.

3.1.2 Translationese

Prior to WMT19, all the test sets included a mix of sentence pairs that were originally in the source language, and then translated to the target language, and sentence pairs that were originally in the target language but translated to the source language. The inclusion of the latter "reverse-created" sentence pairs has been shown to introduce biases into the evaluations, particularly in terms of BLEU scores (Graham et al., 2020), so we avoid it where possible. As detailed in Section 2, most of our test sets do not include reverse-created sentence pairs, except when there were resource constraints on the creation of the test sets.

3.1.3 Document Context

Prior to WMT19, the issue of including document context was raised within the community (Läubli et al., 2018; Toral et al., 2018) and at WMT19 a range of DA styles were subsequently tested that included document context. In WMT19, two options were run, firstly, an evaluation that included the document context "+DC" (with document context), and secondly, a variation that omitted document context "−DC" (without document context). This year, for language pairs for which document context was available in the test set, we therefore include this context when evaluating translations for systems. Although we include document context, ratings are nevertheless collected on the segment-level, motivated by the power analysis described in Graham et al. (2019) and Graham et al. (2020). The particular details on how document context is made available to assessors depends on the translation direction, as described in more detail in Sections 3.2 and 3.3 below for translation into English and out of English, resp.

In the following, we use the following abbreviations to describe annotation style: SR+DC for translation direction where assessors rank individual segments (Segment Ranking, SR) and have access to the full document, SR−DC for translation directions where document context is not available and assessors see individual sentences in random order.

Fully document-level evaluation (DR+DC, document-level ranking with document context available) as trialled last year where we asked for a single score given the whole document is problematic in terms of statistical power and inconclusive ties, as shown in Graham et al. (2019); Graham et al. (2020), and we subsequently did not include this approach for any into-English language this year.

As in previous years, the SR−DC annotation is organized into "HITs" (following the Mechanical Turk's term "human intelligence task"), each containing 100 screens.

[5] Past work has investigated the degree to which employment of a reference translation in DA evaluations could introduce bias into evaluation results and showed no significant evidence of reference-bias (Ma et al., 2017).

	Seg Rating + Doc Context (SR+DC)	Seg Rating − Doc Context (SR−DC)
Chinese to English	**M**	
Czech to English	**M**	
German to English	**M**	
Inuktitut to English		**M**
Khmer to English		**M**
Japanese to English	**M**	
Pashto to English		**M**
Polish to English	**M**	
Russian to English	**M**	
Tamil to English	**M**	

Table 7: Summary of human evaluation configurations for monolingual translation for into-English language pairs; M denotes reference-based/monolingual human evaluation in which the machine translation output was compared to human-generated reference

Language Pair	**Sys.**	**Assess.**	**Assess/Sys**
Czech→English	12	10,703	891.9
German→English	13	14,303	1,100.2
Inuktitut→English	11	13,897	1,263.4
Japanese→English	10	11,234	1,123.4
Khmer→English	7	7,944	1,134.9
Polish→English	14	14,146	1,010.4
Pashto→English	6	8,162	1,360.3
Russian→English	12	12,783	1,065.2
Tamil→English	14	8,899	635.6
Chinese→English	17	34,596	2,035.1
Total to-English	116	136,667	1,178.2

Table 8: Amount of data collected in the WMT20 manual evaluation campaign for evaluation into-English; after removal of quality control items.

3.2 Human Evaluation of Translation into-English

A summary of the human evaluation configurations run this year in the news task for into-English language pairs is provided in Table 7.

In terms of the News translation task manual evaluation for into-English language pairs, a total of 654 turker accounts were involved.[6] 654,583 translation assessment scores were submitted in total by the crowd, of which 166,868 were provided by workers who passed quality control.

System rankings are produced from a large set of human assessments of translations, each of which indicates the absolute quality of the output of a system. Table 8 shows total numbers of human assessments collected in WMT20 for into-English language pairs contributing to final scores for systems.[7]

[6]Numbers do not include the 2,233 workers on Mechanical Turk who did not pass quality control.

[7]Number of systems for WMT20 includes three "human" systems comprising human-generated reference translations used to provide human performance estimates.

3.2.1 Crowd Quality Control

We run two configurations of DA, one with document context, segment-rating with document context (SR+DC), for languages for which this information was available and one without document context, for the remainder, segment rating without document context (SR-DC). We describe quality control details and both methods of ranking systems for into-English language pairs in detail below.

Standard DA HIT Structure (SR−DC) In the standard DA HIT structure (without document context), three kinds of quality control translation pairs are employed as described in Table 9: we repeat pairs expecting a similar judgment (Repeat Pairs), damage MT outputs expecting significantly worse scores (Bad Reference Pairs) and use references instead of MT outputs expecting high scores (Good Reference Pairs). For each of these three types, we include the MT output, along with its corresponding control.

In total, 60 items in a 100-translation HIT serve in quality control checks but 40 of those are regular judgments of MT system outputs (we exclude assessments of bad references and ordinary reference translations when calculating final scores). The effort wasted for the sake of quality control is thus 20%.

Also in the standard DA HIT structure, within each 100-translation HIT, the same proportion of translations are included from each participating system for that language pair. This ensures the final dataset for a given language pair contains roughly equivalent numbers of assessments for each participating system. This serves three purposes for making the evaluation fair. Firstly, for the point estimates used to rank systems to be reliable, a sufficient sample size is needed and the most efficient way to reach a sufficient sample size for all systems is to keep total numbers of judgments roughly equal as more and more judgments are collected. Secondly, it helps to make the evaluation fair because each system will suffer or benefit equally from an overly lenient/harsh human judge. Thirdly, despite DA judgments being absolute, it is known that judges "calibrate" the way they use the scale depending on the general observed translation quality. With each HIT including all participating systems, this effect is

Repeat Pairs:	Original System output (10)	An exact repeat of it (10);
Bad Reference Pairs:	Original System output (10)	A degraded version of it (10);
Good Reference Pairs:	Original System output (10)	Its corresponding reference translation (10).

Table 9: Standard DA HIT structure quality control translation pairs hidden within 100-translation HITs, numbers of items are provided in parentheses.

averaged out. Furthermore apart from quality control items, HITs are constructed using translations sampled from the entire set of outputs for a given language pair.

Document-Level DA HIT Structure (SR+DC) Collection of segment-level ratings with document context (Segment Rating + Document Context) involved constructing HITs so that each sentence belonging to a given document (produced by a single MT system) was displayed to and rated in turn by the human annotator.

Quality control items for this set-up was carried out as follows with the aim of constructing a HIT with as close as possible to 100 segments in total:

1. All documents produced by all systems are pooled;[8]

2. Documents are then sampled at random (without replacement) and assigned to the current HIT until the current HIT comprises no more than 70 segments in total;

3. Once documents amounting to close to 70 segments have been assigned to the current HIT, we select a subset of these documents to be paired with quality control documents; this subset is selected by repeatedly checking if the addition of the number of the segments belonging to a given document (as quality control items) will keep the total number of segments in the HIT below 100; if this is the case it is included; otherwise it is skipped until the addition of all documents has been checked. In doing this, the HIT is structured to bring the total number of segments as close as possible to 100 segments in total within a HIT but without selecting documents in any systematic way such as selecting them based on fewest segments, for example.

4. Once we have selected a core set of original system output documents and a subset of them to be paired with quality control versions for each HIT, quality control documents are automatically constructed by altering the sentences of a given document into a mixture of three kinds of quality control items used in the original DA segment-level quality control: bad reference translations, reference translations and exact repeats (see below for details of bad reference generation);

5. Finally, the documents belonging to a HIT are shuffled.

Construction of Bad References As in previous years, bad reference pairs were created automatically by replacing a phrase within a given translation with a phrase of the same length, randomly selected from n-grams extracted from the full test set of reference translations belonging to that language pair. This means that the replacement phrase will itself comprise a mostly fluent sequence of words (making it difficult to tell that the sentence is low quality without reading the entire sentence) while at the same time making its presence highly likely to sufficiently change the meaning of the MT output so that it causes a noticeable degradation. The length of the phrase to be replaced is determined by the number of words in the original translation, as follows:

Translation Length (N)	# Words Replaced in Translation
1	1
2–5	2
6–8	3
9–15	4
16–20	5
>20	$\lfloor$ N/4 $\rfloor$

3.2.2 Annotator Agreement

When an analogue scale (or 0–100 point scale, in practice) is employed, agreement cannot be measured using the conventional Kappa coefficient, ordinarily applied to human assessment when judgments are discrete categories or preferences. Instead, to measure consistency we fil-

[8] If a "human" system is included to provide a human performance estimate, it is also considered a system during quality control set-up.

ter crowd-sourced human assessors by how consistently they rate translations of known distinct quality using the bad reference pairs described previously. Quality filtering via bad reference pairs is especially important for the crowd-sourced portion of the manual evaluation. Due to the anonymous nature of crowd-sourcing, when collecting assessments of translations, it is likely to encounter workers who attempt to game the service, as well as submission of inconsistent evaluations and even robotic ones. We therefore employ DA's quality control mechanism to filter out low quality data, facilitated by the use of DA's analogue rating scale.

Assessments belonging to a given crowd-sourced worker who has not demonstrated that he/she can reliably score bad reference translations significantly lower than corresponding genuine system output translations are filtered out. A paired significance test is applied to test if degraded translations are consistently scored lower than their original counterparts and the p-value produced by this test is used as an estimate of human assessor reliability. Assessments of workers whose p-value does not fall below the conventional 0.05 threshold are omitted from the evaluation of systems, since they do not reliably score degraded translations lower than corresponding MT output translations.

Table 10 shows the number of workers participating in the into-English translation evaluation who met our filtering requirement in WMT20 by showing a significantly lower score for bad reference items compared to corresponding MT outputs, and the proportion of those who simultaneously showed no significant difference in scores they gave to pairs of identical translations. We removed data from the non-reliable workers in all language pairs.

3.3 Human Evaluation of Translation out-of-English

Human evaluation of out-of-English translations features a bilingual/source-based evaluation campaign that enlists the help of participants in the shared task. As usual, each team was asked to contribute around 8 hours annotation time, which we estimated at 16 HITs per each primary system submitted, with each HIT including 100 segment translations. Unfortunately, not all participating teams were able to provide requested number of assessments, hence, to collect the required number of assessments per MT system, we also employed external translators in a separate campaign. The contracted translators contributed with one third of total number of assessments. Both campaigns utilized document-level DA and were run for all out-of-English language pairs, which test sets include document-level segmentation.

For English→Khmer, English→Pashto, French→German, and German→French, whose test sets do not provide document boundaries, segment-level DA evaluation without document context (SR–DC) was performed, enlisting the effort of translators.

For English→Inuktitut, since we expected no participants to speak Inuktitut, the NRC hired native speakers through the Pirurvik Centre to conduct most of the DA evaluation. Due to the delays in starting the evaluation campaign, they were only able to complete the evaluation a few days before the conference, and could only annotate the news half of the test set. The Hansard half of the test set was not assessed in time for this report, but plans are being made to continue the evaluation after the conference. Updated rankings should be provided at a future date.

In terms of the News translation task document-level manual evaluation for out-of-English language pairs, a total of 1,189 researcher/translator accounts were involved, and 248,597 translation assessment scores were contributed in total (with quality control pairs), including 18,108 document ratings. For the segment-level campaigns (i.e. English→Khmer, English→Pashto, German→French and French→German) we had 300 accounts and 65872 scores collected in total. Statistics per language pair are summarized in Table 11. For data collection we again used the open-source Appraise[9] (Federmann, 2012). The effort that goes into the manual evaluation campaign each year is impressive, and we are grateful to all participating individuals and teams for their work.

3.3.1 Document-Level Assessment

This year's human evaluation for out-of-English language pairs features an improved document-level direct assessment configuration that extends the context span to entire documents for a more reliable machine translation evaluation (Castilho

Total segment-level	31	57,974	1,870.1

Table 11: Amount of data collected in the WMT20 manual document- and segment-level evaluation campaigns for bilingual/source-based evaluation out of English and non-English pairs.

et al., 2020; Laubli et al., 2020). It differs from SR+DC DA introduced in WMT19 (Bojar et al., 2019), and still used in into-English human evaluation this year, where a single segment from a document is provided on a screen at a time, followed by showing the entire document during annotation. Figure 6 shows a screenshot of the document-level direct assessment interface introduced this year.[10] Annotators see the entire document on a screen. In the default scenario, an annotator scores individual segments one-by-one and, after scoring all of them, on the same screen, the annotator then judges the translation of the entire document displayed. Annotators can, however, revisit and update scores of previously assessed segments at any point of the annotation of the given document.

3.3.2 Quality Control

For the document-level evaluation of out-of-English translations, HITs were generated using the same method as described for the SR+DC evaluation of into-English translations in Section 3.2.1 with minor modifications. Source-based DA allows to include human references in the evaluation as another system to provide an estimate of human performance. Human references were added to the pull of system outputs prior to sampling documents for tasks generation. If multiple references are available, which is the case for English→German (3 alternative reference translations, including 1 generated using the paraphrasing method of Freitag et al. (2020)) and English→Chinese (2 translations), each reference is assessed individually.

Since the annotations are made by researchers and professional translators who ensure a bet-

[10] Compare with Figures 3 and 4 in Bojar et al. (2019).

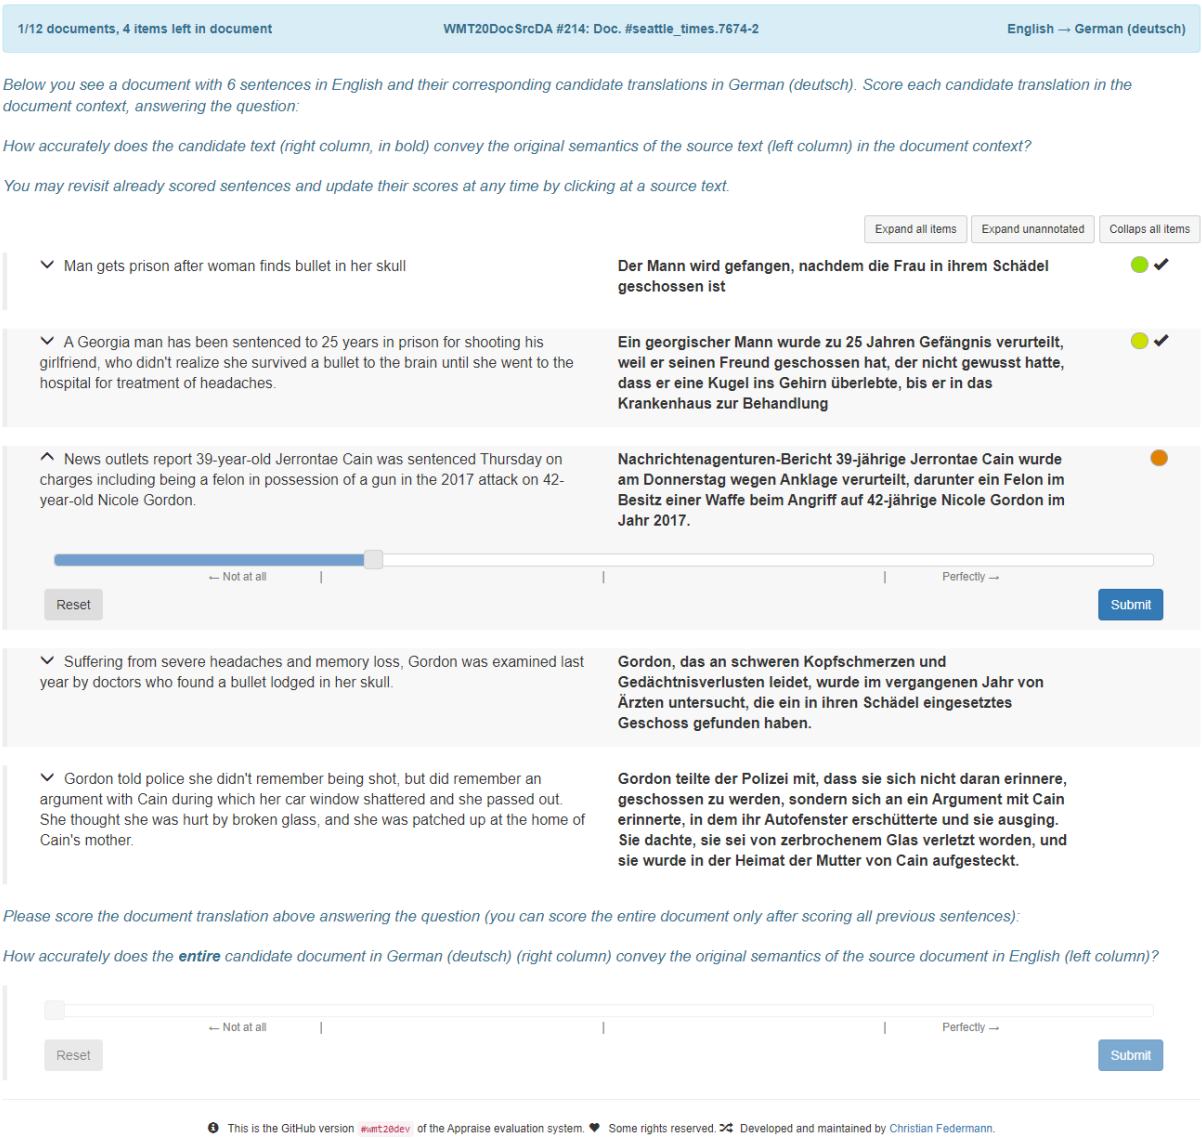

Figure 6: Screen shot of the new document-level DA configuration in the Appraise interface for an example assessment from the human evaluation campaign. The annotator is presented with the entire translated document randomly selected from competing systems (anonymized) and is asked to rate the translation of individual segments and the entire document on sliding scales.

ter quality of assessments than the crowd-sourced workers, only bad references are used as quality control items. Instead of sampling initial documents with close to 70 segments, we sample documents with 88 segments, and then a subset of documents with around 12 segments is selected to be converted into bad references. The remaining of the HIT creation process remains the same.

3.4 Producing the Human Ranking

In all set-ups, similar to previous years, system rankings were arrived at in the following way. Firstly, in order to iron out differences in scoring strategies of distinct human assessors, human assessment scores for translations were first standardized according to each individual human assessor's overall mean and standard deviation score. This year all rankings for to-English translation were arrived at via segment ratings (SR−DC, SR+DC), average standardized scores for individual segments belonging to a given system were then computed, before the final overall DA score for a given system is computed as the average of its segment scores (Ave z in Table 12). Results are also reported for average scores for systems, computed in the same way but without any score standardization applied (Ave % in Table 12).

Table 13 shows official news task results for translation out of English, where lines indicate

Table 12: Official results of WMT20 News Translation Task for translation into-English. Systems ordered by DA score z-score; systems within a cluster are considered tied; lines indicate clusters according to Wilcoxon rank-sum test $p < 0.05$; grayed entry indicates resources that fall outside the constraints provided.

clusters according to Wilcoxon rank-sum test $p < 0.05$. For evaluation of English→Inuktitut insufficient data resulted in a small sample size of human assessments per system and as a result some systems that fall within the same cluster are likely to do so simply due to low statistical power (Graham et al., 2020).

Human performance estimates arrived at by evaluation of human-produced reference translations are denoted by "HUMAN" in all tables. Note that "HUMAN-P" is a human-produced paraphrase of HUMAN-A, according to the method proposed by Freitag et al. (2020). Clusters are identified by grouping systems together according to which systems significantly outperform all others in lower ranking clusters, according to Wilcoxon rank-sum test.

Appendix A shows the underlying head-to-head significance test official results for all pairs of systems. All data collected during the human evaluation is available at `http://www.statmt.org/wmt20/results.html`.

In terms of human and machine quality comparisons in results, it is clear from the source-based evaluation of English to German and English to Chinese translation that human translators vary in performance, with each human translator represented in a distinct cluster. Without taking from the significant achievement of systems that have tied with a human translator, this fact should be taken into account when drawing conclusions about human parity. A tie with a single human translator should not be interpreted as a tie with human performance in general.

4 Test Suites

"Test Suites" have now become an established part of WMT News Translation. Their purpose is to complement the standard one-dimensional manual evaluation. Each test suite can focus on any aspect of translation quality and any subset of language pairs and MT systems.

Anyone can propose their own test suite and take part, and we also try to solicit evaluation from past successful test suite teams to support some cross-year insight.

Each team in the test suites track provides source texts (and optionally references) for any language pair that is being evaluated by WMT News Task. We shuffle these additional texts into the inputs of News Task and ship them as inputs to MT system developers jointly with the regular news texts. The shuffling happens at the document or sentence level as agreed with the test suite authors. (Shuffling at the level of sentences can lead to a very high number of documents in the final test set because each sentence is treated as a separate document.)

MT system developers may decide to skip these documents based on their ID but most of them process test suites along with the main news texts. After collecting the output translations from all WMT News Task Participants, test suites translations are made available back to the test suite authors for evaluation. Test suite sentences do not go through the manual evaluation as described in Section 3.

As in the previous years, test suites are not limited to the news domain, so News Task system may actually underperform on them.

4.1 Test Suite Details

The following paragraphs briefly describe each of the test suites. Please refer to the respective paper for all the details of the evaluation.

4.1.1 Covid Test Suite TICO-19

The TICO-19 test suite was developed to evaluate how well can MT systems handle the newly-emerged topic of COVID-19. Accurate automatic translation can play an important role in facilitating communication in order to protect at-risk populations and combat the *infodemic* of misinformation, as described by the World Health Organization. The test suite has no corresponding paper so its authors provided an analysis of the outcomes directly here.

The submitted systems were evaluated using the test set from the recently-released TICO-19 dataset (Anastasopoulos et al., 2020). The dataset provides manually created translations of COVID-19 related data. The test set consists of PubMed articles (678 sentences from 5 scientific articles), patient-medical professional conversations (104 sentences), as well as related Wikipedia articles (411 sentences), announcements (98 sentences from Wikisource), and news items (67 sentences from Wikinews), for a total of 2100 sentences.

Table 15 outlines the BLEU scores by each submitted system in the English-to-X directions, also breaking down the results per domain. The analysis shows that some systems are significantly more prepared to handle highly narrow-domain data. In

addition, the variance of the output quality across languages and across domains highlights the importance of building MT systems that can generalize across domains.

4.1.2 Document Coherence Check via Markable Annotation (Zouhar et al., 2020)

The test suite provided in 2020 by the ELITR project (Zouhar et al., 2020) follows upon Vojtěchová et al. (2019). The focus this year is on "markables", i.e. mainly domain-specific terms that have to be translated consistently and unambiguously throughout the whole document (except news where style may require variation) to maintain lexical coherence. Manual annotation of the translation of markables is contrasted with manual annotation of fluency and adequacy and also BLEU scores.

The test suite is limited to 4 English→Czech documents and 2 Czech→English documents, covering 215 markable occurrences across 4 different domains. The set of markables was collected in the first phase of the annotation, which amounted to 4k assessments across the systems. The second annotation phase with 6.5k assessments compared markable translations, always checking outputs of all the 13 competing MT systems but still considering the document-level context of each of them.

Among other things, the observations indicate that the better the system, the lower the variance in manual scores. Markables annotation then confirms that frequent errors like bad translation of a term need not be the most severe and conversely, even rare errors such as bad disambiguation, over-translation or disappearance of a term or its translation which conflicts with other terms in the document can be critical.

The comparison of MT outputs with the reference (hidden among MT systems) in the evaluation is also interesting. Man-made errors were always marked as less severe than those of MT. The annotation also suggests that one of the document-level systems outperformed the reference in markable evaluation if error severity and frequency are weighted equally.

Fluency and adequacy collected as average sentence-level scores (with access to the full documents of all systems) are curious, revealing perhaps more about the annotators than the MT systems.

4.1.3 Gender Coreference and Bias (Kocmi et al., 2020)

The test suite by Kocmi et al. (2020) focuses on the gender bias in professions (e.g. physician, teacher, secretary) for the translation from English into Czech, German, Polish and Russian. These nouns are ambiguous with respect to gender in English but exhibit gender in the examined target languages.

The test suite is based on the fact that a pronoun referring to the ambiguous noun can reveal the gender of the noun in the English source sentence. Once disambiguated, the gender needs to be preserved in translation. To correctly translate the given noun, the translation system thus has to correctly resolve the coreference link and transfer information from the pronoun to the noun in the

Table 15: TICO-19 test suite results on the English-to-X WMT20 translation directions.

antecedent (a less common direction of information flow), and then correctly express the noun in the target language. The success of the MT system in this test can be established automatically, whenever the gender of the target word can be automatically identified.

Kocmi et al. (2020) build upon the WinoMT (Stanovsky et al., 2019) test set, which provides exactly the necessary type of sentences containing an ambiguous profession noun and a personal pronoun which unambiguously (for the human eye) refers to it based the situation described. When extending WinMT with Czech and Polish, Stanovsky et al. have to disregard some test patterns but the principle remains.

The results indicate that *all* MT systems fail in this test, following gender bias (stereotypical patterns attributing the masculine gender to some professions and feminine gender to others) rather than the coreference link.

4.1.4 Linguistic Evaluation of German-to-English (Avramidis et al., 2020)

The test suite by DFKI covers 107 grammatical phenomena organized into 14 categories. Since 2018, the same set of phenomena are being tested annually (Macketanz et al., 2018; Avramidis et al., 2019).

Automatic evaluation is complemented with 45 hours of human annotation.

This year, the newcomers VOLCTRANS and TOHOKU-AIP-NTT perform particularly well in the tested phenomena, followed by the traditional systems UEDIN, ONLINE-B, ONLINE-G, and ONLINE-A.

The generally good news is that systems which participated in both WMT19 and WMT20 show an improvement this year. Given that the test suite target side remains undisclosed, these scores can be deemed absolute, unlike the official DA scores which are only relative within each year and set of systems.

The test suite allows to report these improvements per linguistic category and specifically for each MT system that participated in two consecutive years. The biggest improvements are observed in long distance dependencies or interrogatives, verb valency, ambiguity and punctuation, and we tend to attribute all these improvements to increased capacity (which allows increased sensitivity to long-range relations) of the models.

4.1.5 Word Sense Disambiguation (Scherrer et al., 2020b)

Scherrer et al. (2020b) is a followup of last year's evaluation (Raganato et al., 2019), assessing the ability of MT systems to disambiguate a word given its context of the sentence.

The underlying MuCoW (multilingual contrastive word sense disambiguation) dataset contains approximately 2k to 4k sentences per language pair selected from large parallel corpora to contain particularly ambiguous words.

This year, the focus was on language pairs that appeared both in WMT19 and WMT20 (and were available in the MuCoW dataset), namely English→Czech, English↔German, and English→Russian.

Comparing overall numbers across the years, Scherrer et al. (2020b) report that ambiguous words are correctly disambiguated in the majority of cases. Both precision (percentage of correct choices out of sentences where either good or bad expected translation was found) and recall (percentage of correct choices out of all sentences) are above 60 % and reaching 80 % for the best systems in a given language pair when mixing "in-domain" and "out-of-domain" evaluation. The "out-of-domain" synsets are those that are represented in the test suite with more than half of cases coming from the colloquial subtitle domain; other synsets are deemed "in-domain". The "in-domain" scores are generally higher, with precisions above 95 % for the best Czech and Russian systems. Across the years, no real improvement is however observed.

Three cases suggest that training systems at the level of documents decreases their performance in this sentence-level evaluation (each sentence forms a separate document): DocTransformer vs. Transformer by CUNI in 2019 and 2020 and Microsoft document-level vs. sentence-level submission in 2019.

5 Similar Language Translation

Most shared tasks at WMT (e.g. News, Biomedical) have historically dealt with translating texts from and to English. In recent years, we observed a growing interest in training systems to translate between languages other than English. This includes a number of papers applying MT to translate between pairs of closely-related languages, national language varieties, and dialects

of the same language (Zhang, 1998; Marujo et al., 2011; Hassani, 2017; Costa-jussà et al., 2018; Popović et al., 2020). To address this topic, the first Similar Language Translation (SLT) shared task at WMT 2019 has been organized. It featured data from three pairs of closely-related languages from different language families: Spanish - Portuguese (Romance languages), Czech - Polish (Slavic languages), and Hindi - Nepali (Indo-Aryan languages).

Following the success of the first SLT shared task at WMT 2019 and the interest of the community in this topic, we organize, for the second time at WMT, this shared task to evaluate the performance of state-of-the-art translation systems on translating between pairs of languages from the same language family. SLT 2020 features five pairs of similar languages from three different language families: Indo-Aryan, Romance, and South-Slavic. Translations were evaluated in both directions using automatic evaluation metrics presented in this section.

5.1 Data

Training We have made available a number of data sources for the SLT shared task. Some training datasets were used in the previous editions of the WMT News Translation shared task and were updated (Europarl v10, News Commentary v15, Wiki Titles v2), while some corpora were newly introduced (JRC Acquis). The released parallel HI–MR dataset was collected from news (Siripragada et al., 2020), PMIndia (Haddow and Kirefu, 2020) and Indic Wordnet (Bhattacharyya, 2010; Kunchukuttan, 2020a) datasets. All data were initially combined, tokenized using indic-nlp tokenizer (Kunchukuttan, 2020b) and randomly shuffled. From the combined corpus, we randomly extracted 49,434 sentences for the training set and the rest are used as development and test sets. For the South-Slavic language pairs we used large datasets available from Opus (Tiedemann and Nygaard, 2004)[11], more precisely the OpenSubtitles, MultiParaCrawl, DGT and JW300 data. Different to the other language groups, for monolingual data web corpora of the three languages (Ljubešić and Erjavec, 2011; Ljubešić and Klubička, 2014; Erjavec et al., 2015) were given to the participants.

Development and Test Data The development and test sets for Spanish–Catalan and Spanish–Portuguese language pairs were created from a corpus provided by Pangeanic[12]. First, we performed cleaning using CLEAN-CORPUS-N.PERL[13] script to retain sentences that have between 4 and 100 tokens. This narrowed the number of sentences to 1,287 and 1,535 in dev and test sets respectively. Finally, sentences containing metadata information were removed, which resulted in 1,283 and 1,495 sentences in dev and test sets respectively.

The aforementioned shuffled combined HI–MR dataset, 1411 sentences are used for development set and 3882 for the test set. Finally, the test set was equally split into two different test sets: 1941 sentences used for HI to MR and 1941 sentences were used for MR to HI.

For the Slovene–Croatian and Slovene–Serbian language pairs, development and test data were obtained from the Ciklopea translation agency[14] in form of a data donation from the Bisnode business intelligence company[15]. The data consists of public relations releases translated in various directions between the three languages. The data was cleaned, deduplicated and shuffled, resulting in 2,457 dev and 2,582 instances for the Slovene–Croatian pair, and 1,259 dev and 1,260 test instances in the Slovene–Serbian pair. Given that these translations sometimes form Slovene–Croatian–Serbian triangles, special care was invested in circumventing data leakage between development data on one side, and test data on the other, of the two language pairs.

5.2 Participants and Approaches

The second edition of the WMT SLT task attracted 68 teams who signed up to participate in the competition and 18 of them submitted their system outputs. In the end of the competition, 14 teams submitted system description papers which are referred to in this report. Table 22 summarizes the participation across language pairs and translation directions and includes references to the 14 system description papers.

Next we provide summaries for each of the entries we received:

A3-108 The team A3-108 submitted their system for HI–MR and MR–HI. The team initially

build SMT models for both language direction after three steps preprocessing: (i) default – indic_nlp_library[16] and moses tokenizer[17], (ii) morfessor[18] and (iii) BPE[19]. These SMT models were used for back-translation. Finally, these back-translation data were used to train their NMT system.

ADAPT-DCU The ADAPT-DCU team participated in the SLT task on the Croatian–Slovene and Serbian–Slovene language pairs. The team's submissions were based on the Sockeye implementations of the Transformer, with a joint 32k-large BPE vocabulary for all three languages. The submission were regularly multilingual (having Slovene on one side and Croatian and Serbian on the other). The team used only OpenSubtitles bilingual training data, considering other available data to be too noisy. The basic implementation of the multilingual system was submitted as the second contrastive system, the multilingual implementation trained on filtered parallel data as the first contrastive system, while the primary submission included backtranslation of target monolingual data of segments similar to the development data. By performing n-gram-character-based filtering of training data the training time was cut in half with a minor improvement on the translation quality, while the largest improvements in translation quality were obtained by back-translating data similar to development data (between 8 and 14 BLEU points).

f1plusf6 During preprocessing as Marathi and Hindi are rich in terms of morphology, Applied two way segmentation as preprocessing, first supervised and unsupervised word based morphological segmentation and then BPE based segmentation to tackle low-resource language pairs. The participants used shared vocab across training and utilised POS based features on the source side to create initial models for both directions.

For preparing unsupervised back-translation parallel data they used aligned embedding space to generate word by word parallel sentences for both language directions. They also prepared initial models from the provided parallel data for back translation from monolingual data and pruned back-translation pairs based on perplexity score. Their model is based on Luong's attention on bi-LSTM network, copy attention on dynamically generated dictionary with label smoothing and dropouts to reduce overfitting.

Fast-MT Fast-MT team submitted their NMT system where Transformers and Recurrent Attention models are effectively used. They combined the recurrence based layered encoder-decoder model with the Transformer model. Their submitted system for Indo-Aryan Language (Hindi to Marathi) pair is trained on the parallel corpus of the training dataset provided by the organizers.

IIAI IIAI TEAM participate in both directions of the Hindi–Marathi translation task. Their primary submission is a transformer model trained on the released parallel and back-translated monolingual data. The team jointly learned BPE from the merged source–target corpus. After BPE, sentences were corrupted and reconstructed using the two ways:(i) 15% of the subwords in the sentence are randomly selected and masked, (ii) 15% of the subwords are randomly selected one by one and swapped with another randomly-selected subword in the sequence.

Table 22: The teams that participated in the SLT 2020 task and their system description papers.

IITDELHI Team IITDELHI participated in the SLT task on Hindi–Marathi and Spanish–Portuguese language pairs. The team's primary submission builds on fine-tuning over pretrained mBART. They used pre-trained weights of the mBART model (Liu et al., 2019), which is pre-trained on large amounts of monolingual data for 25 languages including Spanish, however Portuguese is not there. The authors initialized a Transformer architecture with 12 encoder and decoder layers using the pre-trained weights, and then directly fine-tuned with the released training data. The authors conclude that mBART is helpful for transfer learning, even though the languages that are not available in the pre-trained model.

INFOSYS Infosys system for Hindi–Marathi (Primary) task is designed to learn the nuances of translation of this low resource language pair by taking advantage of the fact that the source (Hindi) and target (Marathi) languages are same alphabet languages. This system is an ensemble of FairSeq model built on anonymized parallel data and FairSeq back-translation model. The common words/tokens between source and target languages are anonymized during pre-processing upon which the FairSeq model is trained. The input statements during inferencing are anonymized based on the vocabulary of common tokens prepared during training and the predicted statements are de-anonymized during post-processing accordingly. This improved the accuracy (BLEU) of FairSeq considerably. Pre-processing also applies traditional parallel corpus filtering techniques to clean parallel data followed by domain specific techniques. There were records containing multiple statements delimited by slashes, where the domain specific techniques are applied to transform them in to records that retain only the matching single statement, identified based on its syntactic similarity with its parallel statement. Synthetic data generated with the mono-lingual (Marathi) data during FairSeq back-translation has unknown words (w.r.t parallel data vocabulary), resulting unknown words during prediction, which are downvoted while ensembling.

IPN-CIC This team participated in the Spanish-Portuguese language pair. The systems used the Transformer architecture with a fine-tuning for domain adaptation. The team proposed experiments on the kind of tokens used (words and sub-word units) and the initialization of the word embeddings in the systems using either a random initialization or pre-trained word embeddings.

NICT NICT participated in two language pairs: Hindi–Marathi and Spanish–Catalan, for both translation directions. Their primary submission is an unsupervised NMT system, initialized with a pre-trained cross-lingual language model (XLM), that has been trained using only the monolingual data provided by the organizers. They used the

standard hyper-parameters for training XLM and unsupervised NMT. Their contrastive submission is the same but supervised NMT system trained on the combination of the released bilingual and monolingual data.

NITS-CNLP NITS-CNLP system for HI–MR and MR–HI translation is based on cross-lingual language modelling with masked language modeling and translation language modeling. These language models were pre-trained on monolingual corpus and fine-tuned on parallel data following the architecture of Conneau and Lample (2019) and employing 6 layers with 8 attention heads and with 32 batch size, trained on a single GPU.

NLPRL This system submitted by the NLPRL team for the HI-MR is based on the Transformer approach. The system were trained on only the released parallel corpus. The team used SentencePiece library for preprocessing and set vocabulary size of 5000 symbols for source and target byte-pair encoding, respectively.

NLPRL-BHU The team participated in the HI $\leftrightarrow$ MR language pair. The participants used byte pair encoding to preprocess the data and fairseq library with the GRU-transformer for training.

NUIG-Panlingua-KMI The NUIG-Panlingua-KMI team explored phrase-based SMT, dependecy-based SMT method and neural method (used subword) for Hindi$\leftrightarrow$Marathi language pair.

NUST-FJWU NUST-FJWU system is an extension of state-of-the-art Transformer model with hierarchical attention networks to incorporate contextual information. During training the model used back-translation.

Prompsit This team is participating with a rule-based system based on Apertium (Forcada et al., 2009-11). Apertium is a free/open-source platform for developing rule-based machine translation systems and language technology that was first released in 2005. Apertium is hosted in Github where both language data and code are licensed under the GNU GPL. It is a research and business platform with a very active community that loves small languages. Language pairs are at a very different level of development and output quality in the platform, depending on two main variables: how much funded or in-kind effort has been devoted to it and the nature of the languages itself (the closer, the better).

UBC-NLP The UBC-NLP team participated in the SLT task on all the available language pairs. The team regularly used all the parallel data and trained 6-layer Transformer models based on the Fairseq library. Only for the Slovene–Croatian language pair the team performed back-translation, noticing a 3 BLEU point improvement in the results. This team obtained better results with bilingual than with multilingual models (training a single model for all language groups).

UPCTALP The UPCTALP participated in the Romance pairs. This team made use of the Transformer architecture improved with multilingual, back-translation and fine-tuning techniques. Each of this techniques improved over the previous one.

WIPRO-RIT WIPRO-RIT submitted their system to the SLT 2020 Indo-Aryan track. The presented system is a single multilingual NMT system based on the transformer architecture that can translate between multiple languages. The presented model is inspired from the model described in Johnson et al. (2017). WIPRO-RIT achieved competitive performance ranking 1st in Marathi to Hindi and 2nd in Hindi to Marathi translation among 22 systems.in Hindi to Marathi translation among 22 systems.

5.3 Results

We present results for the three language families: three different language families: Indo-Aryan (Hindi - Marathi), Romance (Spanish - Catalan, Spanish - Portuguese), and South-Slavic (Slovene - Croatian, Slovene - Serbian), all of them in the two possible directions. Like last year edision, the second edition of the Similar Translation Task evaluation was also performed on automatic basis using BLEU (Papineni et al., 2002), RIBES (Isozaki et al., 2010) and TER (Snover et al., 2006) measures. Each language direction is reported in one different table which contain information of the team; type of system, either contrastive (CONTRASTIVE) or primary (PRIMARY), and the BLEU, RIBES and TER results. The scores are sorted by BLEU. In general, primary systems tend to be better than contrastive systems, as expected, but there are some exceptions.

This year we recived major number of participants for the case of Indo-Aryan language group

i.e. Hindi–Marathi (in both directions). We received 22 submissions from 14 teams. The best systems (INFOSYS) based on BLEU for Hindi–Marathi achieved score 18.26, however based on other evaluation matric WIPRO-RIT achieved the best 62.45 RIBES and around 72 TER (see Table 23). While in the other direction Marathi–Hindi the best performing system (WIPRO-RIT) reached 24.53 of BLEU and 66.39 on TER, but based on RIBES score 66.83, IITDELHI performed the best (see Table 24).

Similarly to the previous edition of the SLT shared task, participants could submit systems for the Spanish–Portuguese language pair (in both directions). The best systems for Spanish-to-Portuguese achieved over 32 BLEU and around 52 TER. While in the opposite direction (Portuguese-to-Spanish) the best performing system reached 33.82 of BLEU, but its TER score was 52.41, which is higher than in the case of best performing Spanish-to-Portuguese systems. As the Spanish–Catalan dev and test sets were aligned with Spanish–Portuguese ones, we noticed that the best results for the Spanish–Catalan language pair are in general much better than for Spanish–Portuguese. For Spanish-to-Catalan the best system attained over 86 BLEU and below 8 TER. In the case of Catalan-to-Spanish, the best systems scored around 77 BLEU and less than 15 TER.

A new language group in this year's SLT task is the group of (Western) South Slavic languages - Slovene, Croatian and Serbian, forming two language pairs - Slovene–Croatian and Slovene–Serbian, with one additional twist given the very high mutual intelligibility of Croatian and Serbian. The best systems for Slovene-to-Croatian achieved 36 BLEU and 43 TER, which is significantly worse than the results of the same best-performing system in the opposite direction - 43 BLEU and 36 TER. On the Slovene–Serbian pair a similar phenomenon can be observed - Slovene to Serbian achieving 39 BLEU and 40 TER, while the opposite direction achieves 47 BLEU and 33 TER. The reason for such a significant lack of symmetry is the better performance of the systems translating into Slovene, probably given that (Croatian and Serbian) multi-source translation (into Slovene) is simpler than multi-target translation, which was, finally, propagated to the back-translation procedure, increasing the difference between the directions even further.

5.4 Summary

In this section, we presented the results of the WMT SLT 2020 task. The second iteration of this competition featured data from five language pairs from three different language families: Hindi-Marathi; Spanish-Catalan and Spanish-Portuguese; Sloven-Croatian and Slovene-Serbian. We evaluated the systems translating in both directions of the language pair using three automatic metrics: BLEU, RIBES, and TER. We observed that the performance varies widely between language pairs. For example. the best performing systems trained to translate between Catalan and Spanish in both directions obtained significantly higher results than those trained to translate between other language pairs.

In terms of participation, SLT received system submissions from 18 teams. In the end of the competition, 14 teams wrote system description papers that appear in the WMT proceedings. The list of teams with references to the respective system description paper is presented in Table 22. Finally, short summaries of each entry, based on the description provided by the participants, were also presented in this section.

6 Conclusion

This paper presented the results of WMT20 news translation and similar language translation shared tasks, as well as the extra test suites added to the news translation task. Our main findings rank participating systems in their sentence-level and document-level translation quality, as assessed in a large-scale manual evaluation using the method of Direct Assessment (DA).

For out-of-English language pairs, DA was modified so that the context of the whole document is available while judging individual sentences and assessors are allowed to return to any sentence judgement within the document.

As in previous years, the effect of translationese (translating from a source which itself was produced in translation) was avoided except lower-resourced Inuktitut↔English, Pashto↔English, Khmer↔English, and German↔French by creating reference translations always in the same direction as the MT systems are run. Furthermore, 8 out-of-English language pairs would not need human reference for our evaluation at all because the assessors are evaluating translation candidates bilingually, comparing them to the source

Table 32: Results for Slovene to Serbian translation.

text (as opposed to the reference) in these language pairs. The reference translations are nevertheless included as evaluation, hidden among participating MT systems.

This year, English→German included two independent reference translations and one human-produced paraphrase, and English→Chinese included two references. Each of these translations ended up significantly differing in quality from the other ones. In German↔English and also Chinese→English and English→Inuktitut, some MT systems fall in the same cluster with human translation. The observed variance of human translation quality however demands modesty before making any claims about human parity.

The need for cautious interpretation of the results is also strengthened by the fact that even in English→German and English→Czech where human translation was seemingly significantly surpassed in 2018 and/or 2019, the result is not confirmed this year. Furthermore and similarly to previous year, a test suite this year again suggests that some aspects of translation are not handled by current systems at all. This year all MT systems fall into the gender bias trap (Kocmi et al., 2020) and they tend to make more severe errors than humans (Zouhar et al., 2020).

The results of the task on similar language translation indicate that the performance when translating between pairs of closely-related languages is extremely varied across different language pairs. The best performing systems trained to translate between Catalan and Spanish, for example, obtained significantly higher results in both directions than those trained to translate between other language pairs in terms of BLEU, RIBES, and TER.

Acknowledgments

Translation of the test sets for the News task was sponsored by the EU H2020 projects ELITR and Bergamot (English-Czech), and GoURMET (English-Tamil), by Yandex (Russian-English), Microsoft (Chinese-English and German-English), Tilde (Polish-English), Lingua Custodia (French-German), Facebook (Pashto-English, Khmer-English), the University of Tokyo and NTT (Japanese-English). The human evaluation was co-funded by Google and Microsoft. For the human evaluation of English→Inuktitut, we are grateful for the funding received from the NRC and to the workers of the Pirurvik Centre who did the evaluation. We are also grateful to the many workers who contributed to the

human evaluation via Mechanical Turk. We would like to thank Roland Kuhn for advising on the Inuktitut↔English task organization and the Nunavut Maligaliurvia (Legislative Assembly of Nunavut) and Nunatsiaq News for supplying all the Inuktitut↔English parallel data.

The organizers of the similar languages task would like to thank Ciklopea and Bisnode for the Croatian, Serbian, and Slovene data, and Pangeanic for the Catalan, Portuguese, and Spanish data. The work of the organizers of the similar languages task is supported in part by the Spanish Ministerio de Ciencia e Innovación, through the postdoctoral senior grant Ramón y Cajal and by the Agencia Estatal de Investigación through the projects EUR2019-103819, PCIN-2017-079 and PID2019-107579RB-I00 / AEI / 10.13039/501100011033.

This work was supported in part by Science Foundation Ireland in the ADAPT Centre for Digital Content Technology (www.adaptcentre.ie) at Trinity College Dublin funded under the SFI Research Centres Programme (Grant 13/RC/2106) co-funded under the European Regional Development Fund.

Ondřej Bojar would like to acknowledge the grant no. 19-26934X (NEUREM3) of the Czech Science Foundation for his time as well as co-funding manual annotation.

A Differences in Human Scores

Tables 33–50 show differences in average standardized human scores for all pairs of competing systems for each language pair. The numbers in each of the tables' cells indicate the difference in average standardized human scores for the system in that column and the system in that row.

Because there were so many systems and data conditions the significance of each pairwise comparison needs to be quantified. We applied Wilcoxon rank-sum test to measure the likelihood that such differences could occur simply by chance. In the following tables $\star$ indicates statistical significance at $p < 0.05$, † indicates statistical significance at $p < 0.01$, and ‡ indicates statistical significance at $p < 0.001$, according to Wilcoxon rank-sum test.

Each table contains final rows showing the average score achieved by that system and the rank range according according to Wilcoxon rank-sum test ($p < 0.05$). Gray lines separate clusters based on non-overlapping rank ranges.

B Translator Brief: Sentence-Split News Test Sets

Translator Brief

In this project we wish to translate online news articles for use in evaluation of Machine Translation (MT). The translations produced by you will be compared against the translations produced by a variety of different MT systems. They will be released to the research community to provide a benchmark, or "gold-standard" measure for translation quality. The translation therefore needs to be a high-quality rendering of the source text into the target language, as if it was news written directly in the target language. However there are some constraints imposed by the intended usage:

- All translations should be **"from scratch", without post-editing from MT**. Using post-editing would bias the evaluation, so we need to avoid it. We can detect post-editing so will reject translations that are post-edited.
- Translation should **preserve the sentence boundaries.** The source texts are provided with exactly one sentence per line, and the translations should be the same, one sentence per line.
- Translators should **avoid inserting parenthetical explanations** into the translated text and obviously **avoid losing any pieces of information** from the source text.

We will check a sample of the translations for quality, and we will check the entire set for evidence of post-editing.

The source files will be delivered as text files (sometimes known as "notepad" files), with one sentence per line. We need the translations to be returned in the same format. If you prefer to receive the text in a different format, then please let us know as we may be able to accommodate it.

C Translator Brief: Paragraph-Split News Test Sets

Translator Brief

In this project we wish to translate online news articles for use in evaluation of Machine Translation (MT). The translations produced by you will be compared against the translations produced by a variety of different MT systems. They will be released to the research community to provide a benchmark, or "gold-standard" measure for translation quality. The translation therefore needs to be a high-quality rendering of the source text into the target language, as if it was news written directly in the target language. However there are some constraints imposed by the intended usage:

- All translations should be **"from scratch", without post-editing from MT**. Using post-editing would bias the evaluation, so we need to avoid it. We can detect post-editing so will reject translations that are post-edited.
- Translation should **preserve paragraph or newline boundaries and blank lines.** The source texts are formatted as short paragraphs separated by blank lines. We need this formatting preserved so that we can align the sources and translations.
- Translators should **avoid inserting parenthetical explanations** into the translated text and obviously **avoid losing any pieces of information** from the source text.

We will check a sample of the translations for quality, and we will check the entire set for evidence of post-editing.

The source files will be delivered as text files (sometimes known as "notepad" files). We need the translations to be returned in the same format, ideally with utf8 encoding. If you prefer to receive the text in a different format, then please let us know as we may be able to accommodate it.

Findings of the First Shared Task on Lifelong Learning Machine Translation

Abstract

A lifelong learning system can adapt to new data without forgetting previously acquired knowledge. In this paper, we introduce the first benchmark for lifelong learning machine translation. For this purpose, we provide training, lifelong and test data sets for two language pairs: English-German and English-French. Additionally, we report the results of our baseline systems, which we make available to the public. The goal of this shared task is to encourage research on the emerging topic of lifelong learning machine translation.

1 Introduction

Lifelong learning can be defined as the ability to continually acquire new and retain previous knowledge. This ability characterizes humankind, but it is also reflected in several artificial intelligence systems (Parisi et al., 2019; Biesialska et al., 2020). There are many challenges that have to be solved in order to achieve this goal of continual adaptation, among which catastrophic forgetting (French, 1999) seems to be the most relevant.

Lifelong learning is very useful in the area of machine translation (MT), as it allows MT systems to adapt to new vocabularies and topics, and produce accurate translations across time. Currently, there are no previous works that systematically try to solve the problem. This may be due to the lack of a benchmark to address the challenge (Biesialska et al., 2020).

In this context, the main goal of the shared task on lifelong learning for MT is to develop systems that can self-adapt relying solely on domain expert data and are then freed from the necessity of machine learning expertise. What is more, this shared task also allows to investigate several MT research directions, such as: the continuous training/adaptation techniques; the preparation of additional publicly available corpora and evaluation sets; the active learning methods via a controlled simulated environment; the unsupervised adaptation of MT systems; the document-level approaches and the development and evaluation of MT systems across time.

2 Related work and tasks

As mentioned in the introduction, there are not really any works in MT properly evaluating lifelong learning systems. However, there is a long history of studies in related tasks that are useful for addressing the lifelong learning objective.

Domain adaptation is based on the premise that the system can adapt to a target domain known in advance. This has been widely studied earlier for statistical MT e.g. (Koehn and Schroeder, 2007) and, more recently, for neural MT e.g. (Luong and Manning, 2015)).

Instance-based adaptation exploits similarity between training and inference instances (Li et al., 2018), also in unsupervised scenarios (Farajian et al., 2017). These studies have even led to the creation of adaptive MT commercial toolkits (Federico, 2018). Importantly, in this task there is no target domain data available.

Unsupervised learning focuses on using monolingual corpora to train the translation system, without relying on any parallel corpora (Artetxe et al., 2018; Lample et al., 2018).

Active learning aims at selecting the most useful source sentences from a monolingual set and query their translation. This selection needs to minimize the post-edited cost and maximize the improvement of a finetuned model (Liu et al., 2018).

Interactive learning relies on a joint collaboration between a human and an MT system to obtain

Proceedings of the 5th Conference on Machine Translation (WMT), pages 56–64

high-quality translations while reducing the human effort in the process (Peris et al., 2016).

Our lifelong learning setting differs from both domain and instance-based adaptation, as it depends on the target data (called the lifelong data). The lifelong data set, unlike the training data, is unsupervised. Therefore, it is advisable to use techniques such as unsupervised learning, active learning, or interactive learning to approach the task.

3 Overview of the system and environment

The toolchain developed to evaluate the autonomous systems is described in Figure 1. It is made of four parts:

- the input datasets (purple on Figure 1), see section 3.1;
- the four blocks of the system (green on Figure 1 to be modified to include your own system), see appendix A for more details;
- the user simulation (orange on Figure 1), see section A.5;
- the evaluation blocks (blue on Figure 1), see section 3.2

Note that input datasets, user simulation and evaluation blocks are fixed and guarantee the reproducibility of the experiments. Participants are free to edit the four blocks of the system in order to include their own code. Once your code is included in this toolchain, the system will run automatically and the BEAT platform is responsible for managing the data exchanges between the different blocks of the architecture. Thus, you don't need to take care about the communication between blocks, especially, the interaction between the system and the user simulation is automatic.

3.1 Datasets

Two different datasets are available: the **training** data and what we called **lifelong** data. The **training** data is used to train the preprocessing system (eventually) and the initial system in a supervised way. Source text along with the translation of all documents included in this set are available at any time during the lifelong MT process. Note that no development data is provided, meaning that it is up to the participants to decide how to split the training data into train and development (if one is needed).

This year, we used the Europarl and NewsCommentary corpora as training data as they have document information along with their production dates. This represents between 50M and 58.6M words per language depending on the considered language pair (see details in Table 1).

The **lifelong** data is available in a sequential manner: each document is processed one after the other to simulate the process along time. This data is unsupervised, meaning that no reference translation is provided (they correspond to the data to translate every day). The system has to provide translations for those documents that will be evaluated.

We used the WMT14 English to French and English to German corpus as lifelong learning data. While this allows for comparison with systems that participated in WMT14 News translation shared task, one must keep in mind that the training data is much smaller than what was available for the shared task at the time. The aim here is to demonstrate the effectiveness of the continuous adaptation when compared to a baseline system that does not evolve (lower bound) and the best supervised system (retrained with all available data). In the future, we will extend the lifelong learning data to include that from 2014 up to the most recent one.

Training data (from 01.01.1996 to 31.12.2013)				
	English	French	English	German
#Documents	15218		15472	
#Segments	2308516		2246090	
#Words	55.6M	58.6M	53.6M	50.4M
Lifelong data (newstest2014)				
	English	French	English	German
#Documents	176		164	
#Segments	3003		3003	
#Words	62.3k	69.6k	59.3k	55.1k

Table 1: Statistics of the newstest2014 English-French and English-German corpora.

3.2 Evaluation

The evaluation is performed in the *mt_evaluation* and *BLEU_collate* blocks. The first block is aimed at collecting scoring statistics for the document being currently processed. In our case, it will correspond to the BLEU modified n-gram precisions. The second block will aggregate those statistics along with the penalisation in order to provide a final score for the system.

Each time the user simulation is asked for help,

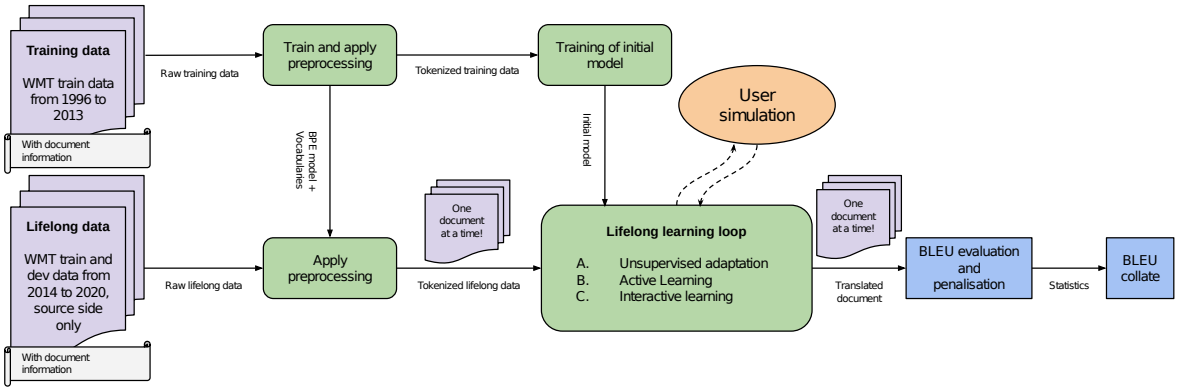

Figure 1: Flowchart of the lifelong learning MT system running on the BEAT platform.

a penalisation is calculated based o the request. The final penalised score S_{pen} corresponds to the following score:

$$S_{pen} = S_{adapt} + (S_{imp} - S_{cor})$$

with S_{adapt} being the score of the adapted system and S_{imp} and S_{cor} are the scores of this system where all sentences requested to the user simulation are considered entirely wrong and correct, respectively. Note that in the case of BLEU, the brevity penalty is not impacted by this calculation, only the correct n-gram counts will be decreased proportionally to the sentence requested for translation. For more details, see (Prokopalo et al., 2020).

4 Baseline systems

Integrating an NMT system in the BEAT platform requires to rethink the code so that everything is done in memory. We chose to use the nmtpytorch toolkit to implement the baseline systems (Caglayan et al., 2017).

Our baseline systems consists of a 2-layer bidirectionnal GRU (Cho et al., 2014) encoder and a 2-layer Conditional GRU decoder (Sennrich et al., 2017) equipped with an attention mechanism (Bahdanau et al., 2014) as implemented in nmtpytorch.

Given a source sequence of embeddings $X=\{x_1, \ldots, x_S\}$ and a target sequence of embeddings $Y=\{y_1, \ldots, y_T\}$, the bidirectional encoder first computes the sequence of annotations corresponding to the concatenation of the hidden states of the two GRU $A=\{a_1, \ldots, a_S\}$. At a given timestep t of decoding, the output layer estimates the probability of the next target word y_t as follows:

$$\begin{aligned} d_t &= \text{GRU}(y_{t-1}, d'_{t-1}) \\ c_t &= \text{Attention}(A, \text{query} \leftarrow d_t) \\ d'_t &= \text{GRU}'(c_t, d_t) \\ o_t &= \tanh(\mathbf{W_c} c_t + \mathbf{W_d} d'_t + \mathbf{W_y} y_{t-1}) \\ l_t &= \mathbf{W_o}(\mathbf{W_b} o_t + b_b) + b_o \\ P(y_t|X, Y_{<t}) &= \text{softmax}(l_t) \end{aligned} \quad (1)$$

For a single training sample, we then maximise the joint likelihood of source and target sentences:

$$\text{L}(X, Y) = \sum_{t=1}^{T} \log\left(P\left(y_t|X, Y_{<t}\right)\right) \quad (2)$$

5 Adaptation techniques

The first adaptation technique used is rather simple. It consists of selecting N sentences from training data that are the closest to the sentences in the document. The chosen similarity metric is the cosine between sentence embeddings obtained by a simple average of word embeddings, as described in (Arora et al., 2017). This data is then used to finetune the initial model for maximum 10 epochs with a learning rate of 0.00004, which is ten times smaller than during initial training of the model.

Furthermore, we employed an active learning strategy as an adaptation method. In principle, there are two steps involved. Firstly, the model provides a translation for each document from the lifelong learning corpus. As the lifelong learning data are unsupervised; therefore, a quality estimation (QE) technique is used to evaluate the quality of the translations without any access to a reference translation. Every document is evaluated

using sentence-level HTER scores (Specia et al., 2018). Secondly, an OpenKiwi QE model (Kepler et al., 2019) is used to rank the sentences according to their quality, and those with the worst HTER score are sent to the user simulation (active learning), which provides the correct translation of the selected sentences. This process implies the penalisation of the BLEU score as explained in Section 3.

6 Experimental setup

The dimensions of embeddings and GRU hidden states are set to 128 and 256, respectively. The embeddings are shared in the decoder (Press and Wolf, 2017). We use ADAM (Kingma and Ba, 2014) as the optimiser and set the learning rate and mini-batch size to 0.0004 and 64, respectively. Regularisation is done by means of a weight decay of $1e{-}5$ and the use of dropout on the embeddings, the source context and the output (set at 0.4) (Srivastava et al., 2014). We clip the gradients if the norm of the full parameter vector exceeds 1 (Pascanu et al., 2013).

The data is processed by a joint BPE model with 30k merge operations (Sennrich et al., 2016a). This leads to respectively 20.7k and 25.1k units for English and French and 17.2k and 26.5k units for English and German, respectively.

We train each model for a maximum of 100 epochs and early stop the training if validation BLEU (Papineni et al., 2002) does not improve for 10 epochs (Figure 2). We also halve the learning rate if no improvement is obtained for three epochs. The number of learnable parameters is around 8.7M for En-Fr and 8.5M for En-De.

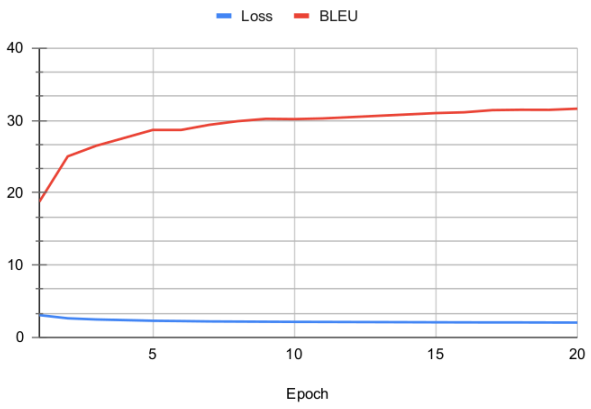

Figure 2: Training loss and BLEU scores for the English→German MT system.

7 Results

The results of the baseline systems and the adapted ones can be found in Table 2.

	English→French	English→German
Baseline		
SHEFFIELD	25.7	15.6
UPC	26.2	14.7
Data selection + finetuning		
SHEFFIELD	26.4	15.5
UPC	26.4	15.1

Table 2: BLEU scores on the newstest2014 English→French and English→German.

Results show that a simple data selection method along with finetuning can provide a small improvement of the system's performance for English to French. German is known to be a more complicated language, as demonstrated by the lower results and the inefficient effect of the adaptation method.

8 Discussion and next year evaluation

We can see that the task, given the very constrained data is very hard. A simple comparison with the results of the systems that participated in the WMT14 News translation task shows more than 10 BLEU points difference. We insist on the fact that the main goal of the challenge is to provide new methods to incrementally adapt the model to incoming documents. Without loss of generality, it is very probable that even with a better baseline system (trained on more data), the adapted models would exhibit a similar improvement.

Many questions and challenges remain open as to how lifelong learning for MT should be implemented. Next year, we ought to push further the evaluation by improving the QE model in order to better select the sentences to be sent to the user Simulation (Active Learning module). Hence, this will require to reconsider how the systems are evaluated. This year, we introduced a way of penalising the systems but without corresponding results.

We hope to have more participants bringing new ideas either by using the current baseline models (and avoiding the integration burden) or by integrating their own systems into the platform.

Acknowledgments

This task is organised by the University of Sheffield (Loic Barrault), University of Le Mans (Fethi Bougares), Universitat Politècnica de Catalunya

(Marta R. Costa-jussà and Magdalena Biesialska) and LNE (Olivier Galibert) in the framework of the EU Chist-ERA funded ALLIES project. A LLMT system

This section describes the four different blocks that compose the LLMT system. The architecture of the system has been developed according to standard MT architectures. In order to facilitate the development of your system and to provide a baseline, a complete implementation of a LLMT system using nmtpytorch (Caglayan et al., 2017) is provided on the evaluation web page, see http://www.statmt.org/wmt20/lifelong-learning-task.html for more details.

General note: the prototypes of the **process** functions **must not** be changed!

A.1 Train and apply preprocessing

This block is responsible for preparing the training data. Preprocessing may include tokenization, learning subword decomposition model, etc. It is also responsible for creating the source and target vocabularies that will be used by the system. To do so, the entire training set is available at once (as in standard training protocol). The prepared training data is sent to the **train initial model** (sec. A.2) block while the subword model and vocabularies are sent to the **apply preprocessing** block (sec. A.3).

```
def process(self, data_loaders, outputs):
        # Get the training data
        data_loader = data_loaders[0]
        for i in range(data_loader.count()):
                (data, _, end_index) = data_loader[i]
                ... data["train_source_raw"].text
                ... data["train_target_raw"].text
                ... data["train_file_info"]
        #Note: setup_for_nmtpytorch(data_loaders) does that for you

        #HERE: DO AS MUCH DATA PREPARATION AS YOU WISH

        #Create vocabulary and BPE or SPM model
        data_dict_tok, src_vocab, trg_vocab, subword_model =
                preprocess(data_dict, self.source_language, self.target_language,
                        self.min_freq, self.short_list)

        data_dict_pickle = pickle.dumps(data_dict_tok).decode("latin1")

        #Write all the necessary outputs
        outputs['train_data_tokenized'].write({'text':data_dict_pickle}, end_index)
        outputs['source_vocabulary'].write({'text':src_vocab}, end_index)
        outputs['target_vocabulary'].write({'text':trg_vocab}, end_index)
        outputs['subword_model'].write({'text':subword_model}, end_index)

        # always return True, it signals BEAT to continue processing
        return True
```

A.2 Train initial model

The initial training of the system is implemented in the file *algorithms/loicbarrault/mt_train_model/1.py*. The process method is the main one. From this method, you can access all the training data from the **train_preprocessing** block. This block outputs a model.

```
# this will be called each time the sync'd input has more data available to be processed
def process(self, data_loaders, outputs):
        (data, _,end_data_index) = data_loaders[0][0]
        data_dict = pickle.loads(data["train_data"].text.encode("latin1"))

        #HERE: USE YOUR SOFTWARE FUNCTIONS TO TRAIN A MODEL

        # The model is Pickled with torch.save() and converted into a 1D-array of uint8
        # Pass the model to the next block
        outputs['model'].write({'value': model}, end_data_index)

        # always return True, it signals BEAT to continue processing
        return True
```

The data is available through the **data_loader**. In the provided baseline system, the processing consists of: tokenizing the data with Moses tokenizers (Koehn et al., 2007), training and applying a BPE model with subword_nmt (Sennrich et al., 2016b). As for the previous block, the **output** is written in the corresponding variable.

A.3 Apply preprocessing

The *apply preprocessing*'s algorithm is defined in the **process** function of the algorithm in *algorithms/loicbarrault/mt_apply_preprocessing/1.py* . The aim is to preprocess the lifelong data similarly to the training data using the vocabularies and subword models trained in the *train preprocessing* block.

The documents from the lifelong learning corpus are provided one after the other in the **input** parameter. Other information from previous blocks is available from the **data_loaders** as before.

```
# this will be called each time the sync'd input has more data available to be processed
def process(self, inputs, data_loaders, outputs):
  #Get the information from previous block,
  #NOTE: this should be done only once and stored in instance variable
  if self.src_bpe is None or self.trg_bpe is None \
        or self.src_vocab is None or self.trg_vocab is None:
    (data, _, end_data_index) = data_loaders[0][0]
    #Source and target vocabularies from the train_preprocessing block
    self.src_vocab = data["source_vocabulary"].text
    self.trg_vocab = data["target_vocabulary"].text
    #Source and target BPE objects to separate text into subwords units
    subword_model = io.StringIO(data["subword_model"].text)
    self.src_bpe = BPE(subword_model, vocab=self.src_vocab)
    self.trg_bpe = BPE(subword_model, vocab=self.trg_vocab)

  # Accessing lifelong data, one document at a time
  lifelong_source_raw = inputs['lifelong_source_raw'].data.text
  lifelong_target_raw = inputs['lifelong_target_raw'].data.text

  #HERE: APPLY THE PREPROCESSING TO THE DOCUMENT
  lifelong_source_tok = ...
  lifelong_target_tok = ...

  #Write all the necessary outputs
  outputs['lifelong_source_tokenized'].write({'text':lifelong_source_tok})
  outputs['lifelong_target_tokenized'].write({'text':lifelong_target_tok})
  if not inputs.hasMoreData():
    # DO SOMETHING WHEN ALL THE LIFELONG DATA HAS BEEN PROCESSED

  # always return True, it signals BEAT to continue processing
  return True
```

A.4 Lifelong learning loop

This block receives the initial model from the mt_train_initial_model block (sec. A.2) and process all files from the lifelong dataset provided by the *apply preprocessing* block, one at a time. This block has access to the whole training dataset and may store every processed document in memory in order to re-use it for further adaptation and/or any processing of your choice.

The output of this block is the translated document. This hypothesis might be obtained by simply translating the source document with the actual model (this is what the baseline model does). Eventually, you will plug your favorite unsupervised/semi-supervised or supervised adaptation scheme to create a better model before translating the document.

This module has also access to the user simulation (sec. A.5) from which the system can get reference translation for some segments in order to provide the best possible output.

A.5 User simulation

This module simulates the human in the loop. It receives requests from your system and provides answers to them. The requests and messages to the human are implemented in the *lifelong loop* block as dictionaries as follows:

```
request = {
  "request_type": "reference",
  "file_id": '{}'.format(file_id),
  "sentence_id": np.uint32(0)
}

message_to_user = {
  "file_id": file_id,  # ID of the file the question is related to
  "hypothesis": current_hypothesis[request['sentence_id']] ,
# The current hypothesis
  "system_request": request,  # the question for the human in the loop
}
```

As for now, only one type of request is available, namely 'reference'. This asks the user simulation to provide a correct translation for sentence number *sentence_id* from document *file_id*.

The answers are also a dict (see below) and can be obtained with the *validate* method as follows.

```
answer = {
  "answer": {"value": self.reference.text[sent_id]},
  "response_type": "reference",
  "file_id": self.file_info.file_id,
  "sentence_id": sent_id
 }
#Get the answer from the user simulation
human_assisted_learning, user_answer = loop_channel.validate(message_to_user)
```

Asking for human assistance is not free and will result in a penalisation of the system score, as described in sec. 3.2.

B How to setup a local platform for system development

B.1 Install

Installing the system requires to have a working conda[1] environment.

Then, the baseline system is available in the following repository: https://github.com/loicbarrault/allies_llmt_beat. Simply install using the *install.bash* script

B.2 Data

The data is available here: https://github.com/loicbarrault/allies_llmt_data. Simply follow the guidelines to recreate the data.

Update the *root_folder* at the bottom of the file *allies_llmt_beat/beat/databases/allies-mt-internal/1.json* with the path to the repository *allies_llmt_data/¡language-pair¿* directory (replace ¡language-pair¿ by the desired language pair, i.e. en-fr or en-de).

B.3 Run

Run the English→French system with the following command:

```
beat --prefix /path/to/git/allies_llmt_beat/beat exp run loicbarrault/loicbarrault/translation_ll_dev/1/translation_ll_dev
```

Run the English→German system with the following command:

```
beat --prefix /path/to/git/allies_llmt_beat/beat exp run loicbarrault/loicbarrault/translation_ll_dev/2/translation_ll_dev
```

Abstract

We report the results of the first edition of the WMT shared task on Chat Translation. The task consisted of translating bilingual conversational text, in particular customer support chats for the English-German language pair (English agent, German customer). This task varies from the other translation shared tasks, i.e. news and biomedical, mainly due to the fact that the conversations are bilingual, less planned, more informal, and often ungrammatical. Furthermore, such conversations are usually characterized by shorter and simpler sentences and contain more pronouns.

We received 14 submissions from 6 participating teams, all of them covering both directions, i.e. En→De for *agent* utterances and De→En for *customer* messages. We used automatic metrics (BLEU and TER) for evaluating the translations of both agent and customer messages and human document-level direct assessments to evaluate the agent translations.

1 Introduction

Despite the significant progress in Neural Machine Translation (NMT) in the last years (Vaswani et al., 2017; Hassan et al., 2018), most systems still operate at sentence-level, disregarding the context of previous sentences. It has been pointed out that ignoring the context may degrade the quality of translations, leading to incorrect choice of pronouns, lexical inconsistency, and incoherence (Läubli et al., 2018; Toral et al., 2018). This is particularly relevant in the context of bilingual chat translation, which normally consists of short messages, referencing each other, and where the correct lexical choice to translate a speaker might have been uttered in a previous turn by the other speaker.

Numerous systems have been proposed recently to address document-level translation (Tiedemann and Scherrer, 2017; Zhang et al., 2018; Maruf et al., 2019; Miculicich et al., 2018; Voita et al., 2019b; Tu et al., 2018; Maruf et al., 2018; Jean et al., 2017; Voita et al., 2018, 2019a; Junczys-Dowmunt, 2019; Lopes et al., 2020), focusing on extending both Long Short-Term Memory (LSTM) (Hochreiter and Schmidhuber, 1997) and Transformer (Vaswani et al., 2017) with additional encoders or decoders to incorporate previous sentences context. However, often, the approaches are developed for single speaker and document-like tasks. By contrast, in this shared task, we focus on the online multispeaker and multi-lingual setting, where each participant in the conversation speaks in their native language. This task has been first considered by Maruf et al. (2018).

In the first round of the Chat Translation shared task, we propose translating dialogues with two speakers, where the first speaker is speaking in the German→English direction and the second is speaking in the English→German. Moreover, we tailor this task for a specific use case: translating conversational text of the customer support chats. In this setting the utterances of the German speaking customer are translated using a machine translation system into English. Then, the replies of the English speaking agent are translated into German and sent to the customer.

Translating conversational text, in particular customer support chats, is an important and challenging application task for machine translation technology. This type of content has so far not been extensively explored in prior MT research, largely due to the lack of publicly available data sets. Prior related work has mostly focused on movie subtitles and European Parliament speeches. To alleviate this problem, we created a corpus for this shared task, ***BConTrasT*** (§2), which is translated from English into German and is based on the monolingual Taskmaster-1 corpus (Byrne et al., 2019).

[*]These authors contributed equally.

Proceedings of the 5th Conference on Machine Translation (WMT), pages 65–75

The main motivation of this shared task is to analyze the challenges posed by conversational data as a content type, which has a broad application in industry-level services. In this content type, the text is usually not carefully well formatted, frequently contains typos, abbreviations, and inconsistent casing, usually with shorter sentences, often informal and ungrammatical. Since chat sessions are interactive, the task of translating conversations can be seen as a two-in-one task, modelling both dialogue and document-level translation at the same time.

In order to evaluate the translation quality of the participating systems we use both automatic metrics (BLEU (Papineni et al., 2002) and TER (Snover et al., 2006)), and human evaluation, consisting of Direct Assessment (DA). For DA, we define the evaluation process similarly to last year's WMT News Translation task (Barrault et al., 2019) with document-level context and following the set of recommendations of Läubli et al. (2020). However, differently than the News task, here we rely on professional translators instead of a crowd. This is mainly based on the observations of Läubli et al. (2020), which provides evidence of the professional translators having better judgment and ability to detect fine-grained phenomena.

Six teams participated in this first campaign of the Chat Translation shared task, with 14 runs in total. All teams submitted both English→German and German→English directions. In §4, we describe each system in more details.

2 Bilingual Conversational Data

One of the main challenges of bilingual conversation translation is the lack of publicly available data sets targeted for the task. The most commonly used datasets are movie subtitles (Lison and Tiedemann, 2016), European Parliament speeches (Koehn, 2005), and conversations extracted from the public forums such as Ubuntu Dialogue corpus (Lowe et al., 2015). These corpora, however, usually involve more than two speakers, contain a significant amount of noise (e.g. speakers information missing in the case of movie subtitles), and usually cover very broad domains.

For the Chat Translation task, we aim to develop a common ground for MT researchers to train and test their solutions by providing common training, validation, and test sets, as well as a common shared task definition. Unfortunately, due to the General Data Protection Regulation (GDPR), most commercial enterprises cannot distribute publicly their proprietary data. Therefore, we opted for using the Taskmaster-1 corpus (Byrne et al., 2019), which includes monolingual (English) task-based dialogues in six domains: (i) ordering pizza, (ii) creating auto repair appointments, (iii) setting up ride service, (iv) ordering movie tickets, (v) ordering coffee drinks, and (vi) making restaurant reservations. We used this corpus for creating the data of our shared task.

Since the main goal of this task is to enable multilingual speakers communicate with each other in their native language, we used the Unbabel translation service [1] to translate the utterances of both speakers into the target language (German). In this process, the conversations (originally in English) were first automatically translated into German and then manually post-edited by Unbabel editors, who are native German speakers. Having the conversations in both languages allows us to simulate bilingual conversations in which one speaker, the *customer*, speaks in German and the other speaker, the *agent*, answers in English. Table 1 shows the first few sentences of a bilingual conversation, along with their corresponding translations. In order to provide a realistic environment in which the amount of in-domain parallel data is scarce, we translated only a small set of the Taskmaster-1 corpus. Since pronouns are one of the main challenges in translating conversational data, we selected the conversations that contain at least one English anaphoric pronoun *it*. For this we used NEURALCOREF [2] and selected around 18k sentence pairs and then divided them into train, development, and test sets (see Table 2).

3 Task Description

A critical challenge faced by international companies today is delivering customer support in several different languages. One solution to this challenge is centralizing support with English speaking agents and having a translation layer in the middle to translate from the customer's language into the agent's (English) and vice versa. The ideal solution for this environment needs to consider the context of both sides which are in different languages, and also needs to be robust to the noisy input since the text here represents a higher degree of noise com-

agent	src: Hi there! How can I help? tgt: Hallo! Wie kann ich helfen?
customer	src: Hey, ich muss mein Auto zum Mechaniker bringen und ich würde gerne Intelligent Auto Imports besuchen. tgt: Hey there, I need to take my car to mechanic and I would like to see Intelligent Auto imports.
agent	src: Sure! what type of car is it? tgt: Sicher! Was für ein Auto ist das?

Table 1: An example of a conversation between a customer and an agent.

	Customer		Agent	
	lines	words	lines	words
Training	6,216	41,492	7,629	70,193
Dev	862	5,805	1,040	9,569
Test	967	6,464	1,133	10,187

Table 2: Statistics of the English side of the training, dev, and test sets.

pared to the cases like news, biomedical, etc. In the first edition of this shared task we focused on this environment and asked the participants to translate the customer's utterances from German into English and the agent's from English into German.

Although participants were encouraged to submit both directions (i.e. modelling both speakers was desired), in this first round of the task, we emphasized on the agent side (English→German) and performed human evaluation in that direction exclusively. This decision is not entrenched and, thus, for future tasks we will aim at evaluating both translation directions. We decided to pursue this direction because the customer side (German→English) suffers from "translationese": English was the original source, and it was recently shown that translationese has a significant impact in evaluation both in automatic metrics (Freitag et al., 2020) and human evaluation (Läubli et al., 2020).

3.1 Data

The main data source for this shared task is ***BConTrasT***. As mentioned in §2, the translated conversations are sampled from the original Taskmaster-1 corpus, and in theory the other monolingual data could be leveraged by the participants either for back-translation or training in-domain language models. However, due to the high degree of sentence similarity within the Taskmaster-1 monolingual corpus, participants were not allowed to use this additional data to train their systems.

In addition to the provided in-domain training data, the participants were allowed to use all the training data provided by the News shared task organizers. Moreover, they were allowed to use existing pre-trained models, such as BERT (Devlin et al., 2018), Transformer-XL (Dai et al., 2019), Reformer (Kitaev et al., 2020), among others.

3.2 Baseline

To define our non-human baseline, we use Facebook's last year submissions to the document-level translation task for both directions (Ng et al., 2019) as the terms of comparison. Even though these models are not domain adapted for the Chat Translation task, we find them to have a reasonable quality for this domain. However, it is worth mentioning that we solely report the results of these models with the automatic metrics and we do not perform any type of direct assessment on these models.

4 Participants

Six participants submitted their systems to the Chat Translation shared task. Although the German→English direction (i.e. customer side) was optional, all participants submitted their systems for both directions. In total, 14 runs were submitted (although only primary submissions were considered for human evaluation). Table 3 summarizes the participants and their affiliations.

Team	Institution
NaverLabs	Naver Labs Europe

Table 3: The participating teams and their affiliations.

4.1 Systems

Here we briefly detail each participant's systems as described by the authors and refer the reader to the participant's submission for further details.

4.1.1 Naver Labs

Naver Labs Europe (NLE) uses a document-level model trained on both the parallel and back-translated data. The authors developed a multi-domain system using the task-specific adapter layers and used it to participate in all the following tasks: chat translation, robustness, and biomedical. These systems are designed to translate both German and English text, or even mixed-language documents. Furthermore, in order to improve the robustness of these systems to noise, the authors applied the following pre-processing solutions: special handling of case with inline casing, a `copy` placeholder for rare characters, synthetic noise generation, and BPE dropout. Their primary submission is an ensemble of three instances of this model, which was used to decode the full bilingual dialogues at once using the entire dialogue's context. The first contrastive submission is a single model with these settings. The second submission is an ensemble of four sentence-level bidirectional models (one of them with masked language model pre-training). For more details see Bérard et al. (2020).

4.1.2 Universities of Edinburgh and Uppsala

The joint submissions of University of Edinburgh and Uppsala University are based on the transformer-big architecture (Vaswani et al., 2017) and rely on fine-tuning pre-existing systems from the WMT 2019 News Translation Task (experiment with both UEdin's submission based on Marian (Junczys-Dowmunt et al., 2018) and Facebook's submission based on Fairseq (Ott et al., 2019)). They are fine-tuned on pseudo-in-domain web crawled data and in-domain task data. The authors also experiment with (i) domain and speaker-level adaptation by automatically tagging the source and target sentences with domain and speaker tags respectively, and (ii) contextual NMT by exploiting the previous context, varying the type and number of previous utterances used. The final submission is an ensemble of four models trained with domain tags and using noisy-channel re-ranking. For more details see (Moghe et al., 2020).

4.1.3 Tao Wang (individual participant)

Individual participant Tao Wang uses a sentence-level system trained on all the WMT20 En-De parallel data. The author uses the Fairseq codebase to train a transformer-big model with the default settings of a base model. Then, the models are fine-tuned with the in-domain training set provided for the Chat Translation shared task.

4.1.4 Tencent

Tencent systems are based on self-attention networks including document-level multi-encoder and sentence-level Transformer. In order to get more in-domain data the authors use a multi-feature data selection method (e.g. FDA, n-gram LM, Transformer LM and BERT) to select data from news corpus. Furthermore, the systems have different fine-tuning strategies, ranging from sentence-level to document-level. Finally, these systems use large scale pre-trained language models including monolingual BERT (Devlin et al., 2018) and bilingual XLM (Lample and Conneau, 2019). For more details see (Wang et al., 2020).

4.1.5 University of Maryland

The University of Maryland systems are both sentence and document-level systems, with two distinct architectures for this task: (i) standard transformer pre-trained on WMT17 News and fine-tuned on the WMT20 Chat data, and (ii) modified transformer by including additional encoder to process one previous utterance in tandem with the current utterance, also pre-trained on WMT17 News and fine-tuned on a mix of WMT20 Chat data and a subset of WMT19 News data. The primary system is based on the first architecture while the second architecture is used for the two contrastive submissions. The contrastive submissions differ in the manner and timing in which training data was processed. For more details see (Bao et al., 2020).

4.1.6 Jordan University of Science and Technology

Mohammed et al. (2020) train separate models for the agent and customer sides after combining the training and development datasets for each side. They use bidirectional RNN (LSTM) with pre-trained BERT (Devlin et al., 2018) embeddings for each of the translation directions. In addition, the authors report using different parameters for training, resulting in different models which then are used for ensemble decoding. For more details see (Mohammed et al., 2020).

4.2 Submission Summary

The submissions for this year's shared task cover different approaches from simple sentence-level to more complex document-level models with extra encoders and decoders to summarize the context

(i.e. previous sentences), and from single direction to bi-directional translations (i.e. jointly modelling both En→De and De→En directions). Moreover, they report different approaches for training their systems ranging from fine-tuning the existing models and using embeddings of the large pre-trained models such as BERT (Devlin et al., 2018) to training the models from scratch.

Not only the submissions are different in their architectures, but they also differ in the data they use during the training. Some use all the available WMT parallel data in addition to the in-domain training data provided for the Chat task, and some apply data selection methods to get more in-domain data to leverage for training their systems.

5 Evaluation Procedures

For the first round of the Chat Translation shared task we follow the standard procedure of WMT shared tasks and evaluate both on automatic metrics and human evaluation with context. Even though automatic metrics provide a cheap mechanism to evaluate Machine Translation (MT) systems outputs, they do not tell the whole story for high-performing systems (Ma et al., 2019). For example, recent "sentence-level human parity" claims do not seem to hold when the context of the document is considered (Läubli et al., 2018), and metrics such as BLEU (Papineni et al., 2002) fail to correlate properly with human assessment (Callison-Burch et al., 2006). In this edition of the shared task, we aim for both automatic and manual evaluations.

5.1 Automatic Evaluation

For the automatic evaluation, we use both BLEU (Papineni et al., 2002) and TER (Snover et al., 2006) metrics. For the former, we use SacreBLEU[3] (Post, 2018), while for TER we use v0.7.25[4] and report case-sensitive scores. The automatic metrics are used to measure the quality of the translations of both sides, i.e. customer and agent.

5.2 Human Evaluation

For the human evaluation we follow a similar procedure to last year's WMT News shared task (Barrault et al., 2019) but take into account the set of recommendations defined by Läubli et al. (2020).

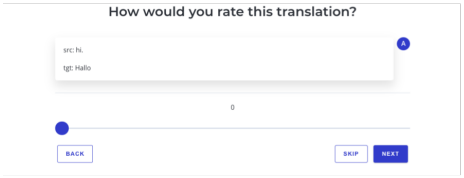
Table 4: Automatic evaluation scores for the agent (En→De) and customer (De→En).

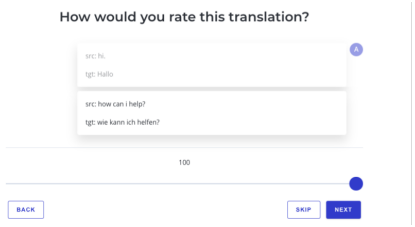
Specifically, we build *HITs* (following the Mechanical Turk's term *human intelligence task*) for the Segment Rating + Document Context (SR+DC) configuration with approximately 100 tasks similarly to WMT News, where both the source and target context is available to the evaluator when rating the actual source and target sentence for evaluation. We use an internal tool at Unbabel which provides the necessary visualization to evaluate a SR+DC configuration. Despite WMT News (Barrault et al., 2019) use Appraise (Federmann, 2012) for the human evaluation as it's tailored for document like text, the tool used for this task was built with chat evaluation in mind and outlines boundaries between each speaker. Figure 1 illustrates the tool used for evaluation.

Following Läubli et al. (2020) guidelines, we use trusted professional translators from the Unbabel community to evaluate the adequacy of the translation on a scale of 0 to 100. The guidelines to the translators were as simple as possible to avoid any type of bias, asking them to rate each sentence taking the context into account and penalizing when there is a context error, as they would for a non-contextual error.

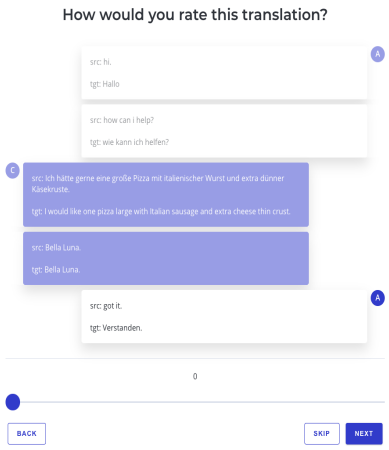
For the first edition of this shared task, we per-



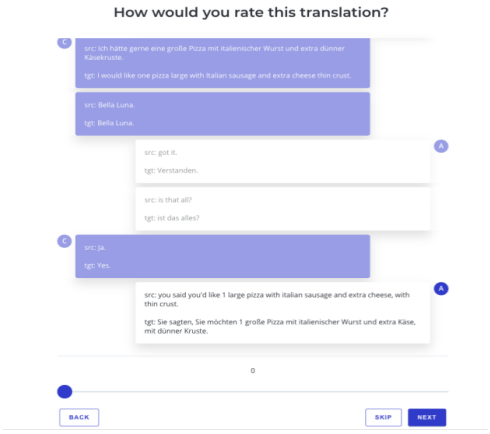
(a) First sentence of the conversation.



(b) Second sentence of the conversation.



(c) Third sentence of the agent in the conversation.



(d) Fifth sentence of the agent in the conversation.

Figure 1: Screenshots of a segment-rating with document-level context using the direct assessment tool. Multiple screenshots are presented to illustrate the iterative nature of the evaluation and how the agent and customer directions are presented as the conversation flows. Note that only the agent side is assessed and the scores are just illustrative.

formed human assessment on the agent side exclusively. Our decision is due to a limitation in the process of data creation, the *customer* direction is from professionally translated German (yet translated nonetheless) to the noisy original English (e.g. typos). Therefore, if we proceed with the evaluation as it stands we would induce two biases, 1) assessing a softer version of *translationese* as the source would be a translation, and 2) the noisy reference could bias the evaluators to rank the systems higher due to the noise and not quality. Both biases could be misleading and impacting their evaluations as professional translators are more sensitive to fine-grained phenomena (Läubli et al., 2020; Barrault et al., 2019). Moreover, in the proposed setting the impact of the noisy context for the agent is negligible for them to have a gist of the message; however there is an extra responsibility in translating the agent since the application of these systems in industry carries an additional factor: it has the company brand associated. Therefore, we preferred to focus more on evaluating the agent translations more rigorously than to spend resources in evaluating the customer.

5.2.1 Protocol for building HITs

We follow a hybrid between WMT News and Läubli et al. (2020) to build HITs. Specifically, as we resorted to professional translators there are fewer control tasks in every 100 HITs (i.e. 5% of the tasks being control tasks). To create a control task, we take inspiration from both the aforementioned resources and perform the following, assuming there is a vocabulary containing all the target words of the conversation: For the very short sentences containing one or two words we replace their words with some random words from the conversation's vocabulary. In the case of sentences with three words we replace the second and third words as before while keeping the first word. Finally, for longer sentences we preserve the first and last 10% of the words while randomly reordering the remaining 80% of the middle words. It is also worth mentioning that the corruption is only employed in the current sentence for evaluation and the context is preserved with no change.

When building the HIT bundle, among different options, we followed the same approach as WMT19 New's (Barrault et al., 2019) procedure

for SR+DC: in order to save time of our annotators, we built the HITs such that a sentence belonging to a given document is displayed and rated before the next sentence of the same document for the same participant MT system output. This is specially suited for our task as the conversations have larger contexts via numerous interactions. Similarly to WMT19 News (Barrault et al., 2019), we randomly picked documents from the pool of documents and for each participant retrieved their translations of that document. Next, we randomly picked documents from the pool until the sum of all their sentences was approximately 95 and added the remaining control tasks. For each document in the HIT, we sliced the translated conversation so that the order of the sentences was preserved when presented to the annotator for the SR+DC evaluation.

5.2.2 Evaluated Dialogs

Due to constraints with the annotators, we evaluated a subsample of the full test set. Therefore, we followed the procedure in § 5.2.1 with a budget constraint, where we specified the number of desired sentences and randomly sampled dialogues until the threshold is met (number of sentences). In the end, we evaluated 40% of the *agent* side, as noted in §5.2 we evaluated only this direction.

6 Discussion

The results of the automatic scores of both agent and customer side of all the submitted systems are reported in Table 4. Comparing these scores with our baselines (i.e. FAIR WMT'19 models) shows that in the agent side (En→De) there is a significant difference (i.e. between +3.0 to +17.0 BLEU scores) in the performance of the submitted systems and the baseline. However, comparing the differences between their TER scores reveals that there is a smaller gap between the systems, ranging from +0.2 to -12.9.

On the customer side we observe different behaviours and more diverse scores. In fact, the differences of the BLEU scores of the baseline and the submissions vary from -7.2 up to +12.7. This means that in a few cases our submitted systems fall behind the baseline by -7.2 BLEU scores. The TER scores show a similar behaviour and the differences of the scores of the submitted systems with the baseline varies from +8.2 (in the worst case) to -9.2 (in the case of best performing system). Given the fact that our references for this direction (i.e De→En) contain a higher degree of noise (eg. typos, wrong casings, etc) it is difficult to make a final and strong conclusion for this direction. We plan to investigate this aspect further.

	Agent	
System	**Avg.↑**	**Avg. z.↑**
Human	**91.4**	**0.319**
NaverLabs	88.2	0.165
UEdinUppsala	85.4	0.032
IndTaoWang	83.6	-0.049
UniMaryland	79.3	-0.235
Tencent	74.3	-0.474
UJordan	63.9	-0.966

Table 5: Human evaluation scores of the agent side.

Table 5 depicts the human evaluation scores (**Avg.**) and the normalized z-scores (**Avg. z**) of the agent side of the primary submissions. Human performance estimates are analogous to Barrault et al. (2019), evaluation of human-produced reference translations are denoted by "HUMAN" in all tables. There are three main clusters of scores, very high scores near human baseline levels (*NaverLabs*, *UEdinUppsala*, and *IndTaoWang*), significant scores (*UniMaryland* and *Tencent*), and lower scores (*UJordan*). Focusing on the high performing systems, we see that *NaverLabs* is the clear winner of the task, followed closely by *UEdinUppsala*, and *IndTaoWang*.

In addition to the overall DA scores of the submissions one might ask how they perform on the more detailed aspects such as sentences with different lengths or sentences containing pronouns. In order to address the first question, we analyzed the human scores for each system with respect to different intervals of lengths (i.e., different bins), namely 1-5 words, 6-10 words, 11-15 words, and, finally, 16+ words. To this end we can condition either (i) on the source sentence, or (ii) on the reference sentence, or (iii) on the generated translations of each system. Among these, we focused on (i) which provides more insights and is fairer comparison for all the systems.

Table 6 presents the human evaluation scores (**Avg.**) and the normalized z-scores (**Avg. z**) of the evaluated submissions in each length range. As we see, all the systems perform similarly in this range, all of them very close to the human reference. It is intersting to note that the submission of *UJordan* outperforms the human reference by +2.5

System	Source length range (words)							
	1-5		6-10		11-15		16+	
	Avg.	Avg. z.	Avg.	Avg. z.	Avg.	Avg. z.	Avg.	Avg. z.
Human	92.5	0.375	**92.5**	**0.367**	**90.0**	**0.254**	85.0	0.012
NaverLabs	92.5	0.375	86.9	0.103	88.3	0.170	**90.0**	**0.234**
UEdinUppsala	92.5	0.375	85.6	0.047	86.7	0.086	65.0	-0.936
IndTaoWang	92.5	0.360	83.1	-0.068	81.7	-0.146	75.0	-0.432
UniMaryland	90.0	0.249	79.4	-0.226	80.0	-0.210	55.0	-1.350
Tencent	85.0	0.042	71.9	-0.586	76.7	-0.378	65.0	-0.906
UJordan	**95.0**	**0.486**	71.3	-0.617	41.7	-2.012	10.0	-3.528

Table 6: Human evaluation scores of the agent side in each length range, based on the source sentences. The systems are ordered based on their general rankings.

	Agent	
System	**DA↑**	**z-score↑**
Human	**95.0**	**0.706**
NaverLabs	85.0	0.220
UEdinUppsala	85.0	0.220
Tencent	80.0	0.043
IndTaoWang	80.0	0.043
UniMaryland	80.0	0.043
UJordan	60.0	-0.861

Table 7: Human evaluation scores for the agent side when there is a pronoun *it* in the source sentence.

and +0.111 points on the average and normalized z-score, respectively. The differences increase by moving to the longer source sentences which is expected. The only unusual observation in these scores is the higher scores of the NaverLabs in the last range (i.e. sentences with 16+ words) in which it outperforms the human reference by +5.0 and +0.222 points on the average and normalized z-score, respectively. This can be due to the evaluators preferences, but still needs further analysis before making any final conclusion.

The English sentences containing pronouns is another aspect that we analyzed further and compared the performances of the submitted systems when there is a pronoun in the sentence. Specifically, we compute the scores for sentences which contain at least one instance of pronoun *it*. Table 7 shows the human scores and the normalized z-scores. As the results show, there is a big difference in the scores obtained by human translators and the submitted systems. In fact, it varies from -10.0 to -50.0 in the case of average score and from -0.486 to -1.567 for the normalized z-scores. Even though the number of tasks is not large, these preliminary results suggest current document-level systems still fall behind humans in challenging linguistic phenomena such as translating pronouns, and require further research for these phenomena.

Finally, we note that three of the submitted primary systems do not leverage the document-level context and use only the sentence-level information. Due to the data size and content proposed for the first edition of the Chat Translation shared task, this is to be expected as there is some level of repetition and similarity among different conversations. However, by looking at the results, we notice that approaches with document-level context seem to benefit from human evaluation when compared to the automatic metrics.

7 Conclusions

We presented the results of the first edition of the WMT20 Chat Translation shared task. For the purpose of this task, we created a bilingual English-German dialogue corpus, ***BConTrasT***, which is publicly available on the website of the task. It is based on the monolingual Taskmaster-1 corpus (Byrne et al., 2019) which was originally created in English. We translated around 18k of conversations of this corpus into German using the professional translators and used it as the in-domain corpus of the shared task.

This year we received 14 submissions from 6 different teams, all of them covering both directions (i.e. *customer* and *agent*). In addition to the automatic metrics (i.e. BLEU and TER) we performed an extensive Direct Assessment with document-level context using professional translators and used the results of these manual evalua-

tions to rank the participating systems. The previous sentences of each conversion provide the annotators with more context to have a more reliable assessment of the translations. Due to the constraints posed by our data, this year we were able to perform the manual evaluation only on the agent side (i.e. En→De). However, we aim at assessing both sides in the futures tasks.

Acknowledgments

We would also like to thank Mathieu Giquel and Ulisses Ferreira for all their help and support during the human evaluation phase, as well as Courtney Stankey for helping in coordinating with the evaluators. This work was supported by the P2020 programs MAIA (contract 045909) and Unbabel4EU (contract 042671), by the European Research Council (ERC StG DeepSPIN 758969), and by the Fundação para a Ciência e Tecnologia through contract UID/50008/2019.

Abstract

We report the findings of the second edition of the shared task on improving robustness in Machine Translation (MT). The task aims to test current machine translation systems in their ability to handle challenges facing MT models to be deployed in the real world, including domain diversity and non-standard texts common in user generated content, especially in social media. We cover two language pairs – English-German and English-Japanese and provide test sets in zero-shot and few-shot variants. Participating systems are evaluated both automatically and manually, with an additional human evaluation for "catastrophic errors". We received 59 submissions by 11 participating teams from a variety of types of institutions.

1 Introduction

In recent years, Machine Translation (MT) systems have seen great progress, with neural models becoming the *de-facto* methods and even approaching human quality in news domain (Hassan et al., 2018). However, like other deep learning models, neural machine translation (NMT) models are found to be sensitive to synthetic and natural noise in input, distributional shift, and adversarial examples (Koehn and Knowles, 2017; Belinkov and Bisk, 2018; Durrani et al., 2019; Anastasopoulos et al., 2019; Michel et al., 2019). From an application perspective, MT systems need to deal with non-standard, noisy text of the kind which is ubiquitous on social media and the internet, yet has different distributional signatures from corpora in common benchmark datasets.

Following the first shared task on Machine Translation (MT) Robustness, we now propose a second edition, which aims at testing MT systems' robustness towards domain diversity. Specifically, this year's task aims to evaluate a general MT system's performance in the following two scenarios:

- Zero-shot: the goal is to evaluate a general MT system's performance in unseen domains at test time, which are likely to be different from a training domain (e.g. News, Wikipedia). For that, no domain-specific data or information on the test sets is given to participants.

- Few-shot: the goal is to test an MT system's performance if a few in-domain training examples are provided for the target domain. The question we ask is: can the general MT system leverage those training examples to improve performance on this domain while not dropping its performance on other domains?

We describe the dataset and the task setup in Section 3. The shared-task attracted a total of 23 submissions from 11 teams. The teams employed a variety of methods to improve robustness. A specific challenge was the small size of the in-domain noisy parallel dataset. We summarize the participating systems in Section 4 and some trends on approaches used by various systems in Section 4.1. The contributions were evaluated both automatically and via a human evaluation and the results discussed in Section 5.

We hope that this task leads to more efforts from the community in building robust MT models.

2 Related Work

Domain mismatch is a key challenge in machine translation (Koehn and Knowles, 2017). Most approaches for improving robustness of MT systems to domain shift assume the existence of significant amounts of parallel data in both the source and target domain. In this scenario, a common approach is to first train an MT system on a (generic) source domain and then to fine-tune it on a (specific) target domain (Luong and Manning, 2015; Freitag and Al-Onaizan, 2016; Servan et al., 2016; Chu

Proceedings of the 5th Conference on Machine Translation (WMT), pages 76–91

et al., 2017), to continuously fine-tune on datasets increasingly similar to the target domain (Sajjad et al., 2017), or to dynamically change the balance of data towards the target domain (van der Wees et al., 2017). Another approach trains a system on multiple domains at the same time, while adding domain-specific tags to the input examples (Kobus et al., 2016). Both these approaches were employed by participants of the first shared task on MT robustness (Li et al., 2019).

Other methods for domain adaptation of MT systems include instance weighting (Wang et al., 2017b), incorporating a domain classifier (Chen et al., 2017; Britz et al., 2017), and data selection (Wang et al., 2017a). Some make use of monolingual data available either in the target domain—for example by training the decoder on such data (Domhan and Hieber, 2017) or by back-translating it (Sennrich et al., 2016)—or in the source domain, via similar techniques (Zhang and Zong, 2016).

Chu and Wang (2018) provide a broad survey of domain adaptation for neural MT, which demonstrates that the predominant setup assumes knowledge of the target domain and availability of target domain data at training time. In light of this prior work, the shared task proposed a relatively under-explored scenario, where examples in the target domain are either unavailable or relatively few.

Other aspects of robustness are robustness to adversarial examples or noisy inputs. The fragility of neural MT models has been previously demonstrated in various settings (Belinkov and Bisk, 2018; Heigold et al., 2017; Anastasopoulos et al., 2019; Lee et al., 2018). Michel and Neubig (2018) proposed a new dataset (MTNT) to test MT models for robustness to the types of noise encountered in the Internet. The previous iteration of the shared task focused on robustness of MT systems to such noise (Li et al., 2019). We refer to that report for more details.

3 Task

To facilitate comparability with the News translation task and also to reduce the participation cost, we suggest the same training data as the WMT20 News task.[1] The focus of the Robustness Task is to both evaluate models built on this type of data on more challenging test sets, as well as to encourage participants to explore novel training and modeling approaches so that models have more robust performance at test time on multiple domains, including unseen and diversified domains. We offer two language pairs: English-German (En→De) and English-Japanese (En→Ja), with different test sets focusing on one or both these language pairs, or one particular language direction.

3.1 Phases

The test cycle is divided into two phases. In the first phase – **zero-shot phase**, we release blind test sets from a mixture of domain(s), and participants submit their system's output without any information on these blind domains or training/development data for them. In the second phase – **few shot phase**, we release a small amount of training data (10K sentence pairs) from one of the test domains and participants submit their system's output after utilizing these training examples.

3.2 Training Data

The task includes two tracks, *constrained* and *unconstrained* depending on whether the system is trained on a predefined training datasets or not. The two tracks are evaluated by the same automatic and human evaluation protocol, however, they are compared separately.

- **Constrained:** Participants can only use the training data made available for this year's News translation task for training. They can use both the parallel data and monolingual data provided in this year's task. Multilingual systems trained with data provided by WMT20 News task are also allowed (and participants should indicate whether this is the case).

- **Unconstrained:** Participants can develop novel solutions to learn from unlabelled data, especially additional monolingual data from domains such as biomedical and/or Reddit. The online systems that we evaluated also fall in this category.

- **Few-shot:** Participants are provided a few in-domain training examples. The data provided consist of the German-English train and valid portions of the CoVoST dataset (deduplicated by source German sentences) and the Japanese-English and English-Japanese

[1] http://www.statmt.org/wmt20/translation-task.html

train and valid portions of the MTNT dataset (Michel and Neubig, 2018).

3.3 Development Data

The task specified the following data to help participants evaluate their system's performance on unseen and multiple domains.

- English-German: participants can use the development data from the News translation task, development data from QED (Abdelali et al., 2014) corpus, development data from WMT19 Medical translation task, and development data from the WMT16 IT translation task.

- English-Japanese: participants can use the development data from the News translation task, and development data from the MTNT dataset, which contains noisy social media texts and their clean translations.

3.4 Test Data

We have three test sets which were created using different sources and approaches. The general statistics are reported in Table 1.

Wikipedia Comments Test Set (set1): This data was collected by Imperial College London and Facebook. We created this to be a particularly challenging test set where the source segments contain various types of linguistic constructs that could lead to what we call *catastrophic errors* in the MT output. For that, we chose user-generated content, namely comments on Wikipedia edits by Wikipedia editors. More specifically, we took English Wikipedia comments from an existing dataset from the Toxic Comment Classification Challenge.[2] The Challenge made available 160,000 comments on Wikipedia edits tagged with multi-grade toxicity labels (toxic, severe toxic, obscene, threat, insult, or identity hate). We believe that the presence of toxic content can be very challenging for MT systems.

After filtering out non-English segments and segments that were too long (>50 words or >1000 characters) or too short (<5 words), we kept all the remaining comments with any toxic label (approx. 7K) and randomly selected 10K non-toxic samples.

Based on this initial selection of 17K English comments, we defined heuristics to further sample from the selection and diversify the potential sources of catastrophic errors. To that end, we first machine translated all comments using an in-house transformer-based model into Japanese and German. The goal of that was to be able to examine potential differences in source and (one example of) translation segments.[3] We then pre-processed and automatically annotated all 17K segments with the following soft labels for catastrophic errors:

1. Introduction of toxicity: we checked both source and machine translation for toxic words (using in-house lists) and labelled as positive (i.e. potentially containing errors) cases where the source does not contain such words, but the translation does (at least one).

2. Mistranslation of named entities: we annotated person, organisation and location named entities in the source and translation (using an in-house named entity recognition model) and labelled as positive cases where (a) the translation has fewer named entities than the source and the translation has at least one toxic word, (b) the translation has at least 2 fewer named entities than the source, and (c) the list of named entity types (e.g. person vs location) in source and translation differ and translation has at least one toxic word.

3. Inversion of sentiment: we applied the Google Cloud Sentiment Analysis tool[4] to annotate each source and machine translation and labelled as positive cases with very different sentiments, i.e. the source is very positive (>0.5) and the translation is very negative (<-0.5) or vice-versa (scores range from -1 (negative) to 1 (positive).

4. Difference in emojis: we detected emojis in the source and machine translation[5] and labelled as positive cases where source and translation have a different number of emojis.

[2] www.kaggle.com/c/jigsaw-toxic-comment-classification-\challenge

[3] We are aware that using one particular translation model can bias the selection to cases that are challenging for this particular model. In future work following this methodology, we recommend that multiple MT models be used.

[4] https://cloud.google.com/natural-language/docs/analyzing-sentiment

[5] https://github.com/carpedm20/emoji/)

5. Presence of idioms: we checked if the source contains idiomatic expressions, using an in-house list of idioms built from various sources, and labelled those cases as positive.

We note that the automatic labelling using our various pre-processing techniques may have introduced errors, but we believe that basing the selection on such heuristics will still lead to higher chances of selecting very challenging source segments than arbitrarily sampling the data.

We divided the original data (toxic and non-toxic 17K) into 5 sets, one for each of these soft labels (allowing for duplicates samples across sets). Finally, we uniformly selected a test set per language pair, containing 1,098 unique segments for English→German and 1,100 unique segments for English→Japanese. We provided the test sets for experiments in both directions, but we will only report results on the original source→target direction. For each of these test sets, we discarded the machine translation and collected reference translations from scratch using professional translators.

Reddit Test Set (set2): This data was collected by Carnegie Mellon University following the same procedure as last year's test set (described in Michel and Neubig (2018)): comments from the social media website `reddit.com` were scraped, filtered for noisy comments and translated by professional translators. This year, data was collected for two translation directions: English→Japanese and Japanese→English. For English, comments were collected from the `/r/all` feed, which encompasses all communities, and filtered for English. Since Japanese is a minority language on Reddit, comments were scraped from a selection of japanese-speaking communities, detailed in Michel and Neubig (2018).

Common Voices Test Set (set3): This data was obtained from from the CoVoST corpus (Wang et al., 2020). CoVoST is derived from Common Voice (Ardila et al., 2020), a crowdsourced speech recognition corpus with an open CC0 license. Transcripts were sent to professional translators and the quality of translations was controlled by automatic and manual checks (Guzmán et al., 2019). For this task, we used the German→English test set with source German sentences deduplicated.

3.5 Evaluation protocol

Automatic evaluation: We first computed BLEU (Papineni et al., 2002) for each system using SacreBLEU (Post, 2018). For all language pairs except En→Ja, we used the original reference and SacreBLEU with the default options. In the case of En→Ja, we used the reference tokenized with KyTea and the option `--tokenize none`.

Human evaluation: The system outputs were evaluated by professional translators. The translators were presented the original source sentence, the reference and the system output side by side. The order between the reference and the system output, as well as the different MT systems, was randomized and not disclosed to the translator. The translators rated both the reference and the translation. We believe that the reference translation in this evaluation setup to serves the purpose of calibration by offering the human annotators one (hopefully) good example of translation. We also report metrics for these reference translations as an upperbound for the data.

We sampled 400 translations from each MT system in each of the test sets and language pairs (28 combinations), resulting in 11,200 segments and their references to be annotated (22,400 segments in total). Each translation/reference segment was annotated by three raters. Quality control was manged by the company providing the ratings, where the main check was that the three ratings could not disagree by more than one category (in which case additional raters are enlisted until agreement is reached).

The rating of translations was done using a different metric from last year's task. Instead of direct assessment (DA), we chose a discrete *likert* rating ranging from 1 to 5, which we found to lead to higher agreement between raters in other annotation projects (Diab et al., 2020). A summary of the guidelines provided for this *likert* rating is as follows:

1 Bad: translation errors are so severe that they cause the target text to be incomprehensible. This may be mainly due to major grammatical, typographical, or lexical errors, or omission of critical or important salient information.

2 Poor: the target text contains translation errors, but these errors do not hinder overall comprehension and do not mistranslate overall intent.

	En→De	De→En	En→Ja	Ja→En
Wikipedia Comments (set1)	1,098 / 26,549	-	1,100 / 29,419	-
Reddit (set2)	-	-	1,376 / 20,011	997 / 20,842
Common Voice (set3)	-	5,609 / 43,119	-	-

Table 1: Number of sentences/words per test set (Japanese words are counted after tokenization with KyTea).

The errors may be mainly due to partial differences in intent, grammatical or typographical errors, or omission of important salient information.

3 Acceptable: the target text is fully comprehensible and fully translated (i.e. no information is omitted), even if it contains minor errors. These errors may be mainly due to partial lack of fluency, or a few grammatical or typographical errors.

4 Very Good: the target text is fully comprehensible, fully correct, and does not miss any information. Style matters may not be transferred faithfully, such as level of formality, or the translation of idioms does not need to be perfect but their meaning needs to be correctly conveyed.

5 Excellent: the target text is fully comprehensible, fully correct, and does not miss any information. Additionally, source style is reflected in the translation and if present, idioms are perfectly handled.

Catastrophic error annotation: As an additional form of human annotation, alongside the *likert* ratings described above, we instructed the annotators to indicate, for translations rated below **3 - poor or bad**, whether they contained any catastrophic errors, and to categorise the type of error. This is a new type of evaluation and we provided detailed guidelines, which we summarise below.

Annotators were asked to provide a **YES/NO flag** to indicate whether the translation contains any error (one or more words) that changes the meaning of the source segment in a critical way. Critical errors are those that lead to misleading translations which may carry religious, health, safety, legal or financial implications, or introduce toxicity. The set of critical errors used for the guidelines (which also included examples of these errors) includes – but is not limited to – the cases below:

- Introduction of toxicity (profanity, violence, hate or abuse) (TOX).
- Introduction of health/safety risks (SAF).
- Mistranslation of named entities (NAM).
- Reverse negation (NEG).
- Reverse of sentiment/polarity (SEN).
- Change in units/time/date/numbers (NUM).
- Other (OTH).

If the answer is YES, annotators were asked select one of the categories indicating the type of critical error. They were asked to choose the category that compromises the meaning of the sentence the most if more than one error was found in the same segment. Three raters flagged and categorized errors.

4 Participants and System Descriptions

We received submissions from 8 teams participating across different tasks, test sets and languages we provided this year. Below we briefly present the systems we were able to get a system description paper for:

Naver Labs (NLE): They participated in Chat and Biomedical tasks along with the Robustness task. They trained a general big-transformer model using *FairSeq* toolkit (Ott et al., 2019) and adapted it towards different tasks using lightweight adapter layers for each task (Bapna and Firat, 2019). They compared results against the more traditional fine-tuning method (Luong and Manning, 2015) to show that the former provides a viable alternative, while significantly reducing the amount of parameters per task. They also explored using embedding from pre-trained language models in their NMT system of which they tried two MLM variants: i) using NMT encoder's setting, using Roberta (Liu et al., 2019). The latter was found more robust to novel domains and noise. The authors found that initializing with first 8 layers instead of the entire model to

be optimal. Another notable finding included the use of single bidirectional model instead of monodirectional models to give similar performance. For the robustness task specifically they added source side synthetic noise and used BPE drop-out. While this was found to be useful in handling noisy data, no gains towards domain robustness were observed.

LIMSI: LIMSI participated in Biomedical and Robustness tasks. For the robustness challenge their main exploration was using adapter layers (Bapna and Firat, 2019) applied on 8 domains (parallel data released in the News task). The architecture adds an additional, domain-specific layer on top of every layer of the encoder and the decoder. This allows the test sets from known domains to use adapter layers and for novel domains to use the generic system. They created a noisy domain by adding synthetic noise to source data. The idea is that residual adapter layer learned from such data learns how to deal with noisy domain and is also able to preserve performance on the cleaner domains. However this did not work as well. The residual adapter fine-tuned using the ParaCrawl corpus gave better performance.

e-Translation: Their effort was mainly directed towards the News translation task, however they submitted two systems to the Robustness task. Their general systems were built using big-transformer configuration trained using Marian (Luong and Manning, 2015) after up-sampling original training data. The system was then fine-tuned for another round with an LM scored subset of original data. Finally ensembling four checkpoints produced their final systems. The authors reported an interesting finding that their models performed better on the noisy test sets released for this task than on the standard news test set, suggesting that systems trained on the diverse domains were already robust enough.

UEDIN: Team UEDIN also mainly trained their system towards News translation task, but added Gumbel noise to the output layer of the systems submitted to the Robustness task. They followed standard NMT training pipeline and boasted their systems with additional data filtered from the paracrawl corpus. The data was carefully selected using dual cross-entropy (Junczys-Dowmunt, 2018) and length-normalized cross-entropy.

OPPO: Team OPPO also trained their systems for the language pairs released for the News translation task and did not carry any specific exploration towards the task of Robustness. Their systems followed standard training regime of training transformer models with Marian toolkit, with back-translation to generate synthetic data and ensembles of models. As additional module, they added to their system a reranker trained on six forward and backward models, the scores of which are used as features in training the reranker.

PROMPT: Team PROMPT also participated mainly in the News translation task. Their systems were trained using OpenNMT (Klein et al., 2017) toolkit. They applied several stages of data preprocessing including length-based filtering, removing duplications, and using in-house classifier based on `Hunalign` aligner to identify and discard non-parallel sentences. They used two types of synthetic data to improve their systems: i) randomly selecting subset of Wikipedia equal to the size of news data and generating parallel corpus through back-translation, ii) creating synthetic data with unknown words using the procedure described in (Pinnis et al., 2017). Systems were trained with tags to differentiate between original data and synthetic data from each other. Named entities were handled through a post-processing module with re-decoding whenever a named entity was not translated or translated incorrectly.

Online systems: We also evaluated three top performing online MT systems, which are also commonly used in the WMT News translation task: online-A, online-B, and online-G. While we do not have access to details of the architectures of these models, to the best of our knowledge they are are all neural MT models with one case including a selection between translations from statistical and neural models.

4.1 Common Trends

Participating systems were trained following a standard recipe, i) using big-transformer models, ii) boasting performance with tagged back-translation, iii) continued training with filtered data and in-domain data (where available), iv) ensembling different models to obtain further improvements. Only two teams, namely Naver Labs and LIMSI made specific efforts towards the task of Robustness. Both of them used lightweight domain adaptors proposed by Bapna and Firat (2019). Both teams

also explored making the systems robust by adding noisy synthetic data. While they found using adaptor layers instead of fine-tuning the entire model to be a viable alternative, no success was observed adding noise to the training process.

5 Results

In this section we describe the results of both automatic and manual evaluation of general translation quality (Section 5.1), as well as an analysis of catastrophic errors (Section 5.2).

5.1 General Quality

Overall, the correlation between human judgments and BLEU is not strong. For En→De (set1), the Pearson's correlation coefficient is 0.97, while for the other four tasks the coefficients are lower, with 0.78, 0.65, 0.52, 0.79 for En→De (set1), Ja→En (set2), En→Ja (set2), and De→En (set3) respectively.

Automatic Evaluation The automatic evaluation (BLEU) results of the Shared Task are summarized in Table 2, where we also include the three online translation systems. We performed significance test using `compare-mt` (Neubig et al., 2019) where systems are considered as significantly different at $p < 0.05$. The result of significance test is used for the automatic evaluation ranking.

Overall, the **unconstrained** online-B system provides strong results and outperforms most systems in the five language pairs, except the De→En (set3) and En→Ja (set1).

Among the participating teams, the best **zero-shot** systems were OPPO, which outperforms other zero-shot systems in En→De (set1), Ja→En (set2), and En→Ja (set2) tasks, and NLE, which outperforms other systems in the other two tasks.

Only Naver Labs participated in the **few-shot** stage (NLE-few) and submitted their systems in four language directions except the En→De (set1) subtask. Their few-shot systems ranked the first in all the four directions they participated, tying online-B system in three language pairs.

Human Evaluation The results of human evaluation following the evaluation protocol described in Section 3.5 are outlined in Table 3. The *likert* score is calculated by averaging ratings from the three human annotators over the 400 sampled translations for each MT system, and we performed significance test using the `testSignificance.py` script[6] (Dror et al., 2018) with $p < 0.05$. The result of significance test in *likert* score is used for the human judgement ranking. Interestingly, the correlation in the system rankings between human judgments and BLEU is not strong. In other words, the best performing systems in BLEU do not rank high according human judgement, sometimes even rank the lowest. For example, in Ja→En (set2), the online-B system ranks first in BLEU but last in *likert* score. OPPO outperforms all systems in both directions on set2, and is overall the best system among the **constrained, zero-shot** submissions.

To get insight on the proportion of sentences with each of the categories of human score, Figure 1 displays the distribution of *likert* ratings for all systems. The most frequent ratings for the participating systems are 2 and 3 while for the human-translated references it is 4. Comparing the few-shot and zero-shot systems, the NLE-few outperforms most systems because the frequency of lower ratings (1 or 2) is lower, but the frequency of high ratings (5) is similar to the zero-shot systems.

5.2 Evaluation on Catastrophic Failures

Here we turn our attention to the extra level of annotation where human raters flag and categorise catastrophic errors in sentences. We note that we had three raters for each translation, and that in some cases different categories of errors were flagged. This naturally happened since the raters were asked to choose the category with the biggest negative impact, which is a subjective decision. For example, in En→De (set1), each system has 28 sentences in average flagged with multiple errors. We report this average multi-error counts in Figure 3. In addition, we note that there may also be cases of disagreement, where only a subset of raters flag errors (we will perform agreement analysis later).

Error rate of systems Table 3 shows the proportion of sentences containing as least one error in (which we will refer as "error rate"). The error rates vary among different test sets. Regarding set1, which is sourced from Wikipedia comments, oversampling for more challenging content, the error rate for different systems is high, ranging from 51% to 76%. It is interesting that annotators indicate that the human-translated references contain catastrophic errors as well, with an error rate of 23% for both language pairs in set1. The error rate in

Table 2: Automatic evaluation (corpus-level BLEU, cased) over all submitted systems, with the system's rank in parentheses ($p < 0.05$). Bold highlights the system with highest BLEU score.

set2, sourced from Reddit, is lower, which is within 36%-51% for participating systems and 16%-18% for the references. In set3, which is sourced from Common Voice data, the error rate is the lowest. All systems except one achieve less than 10% error rate. The issue of catastrophic errors in the reference translations needs further investigation. We speculate that this could be due to misinterpretation of the guidelines, as we discuss below.

The error rate is highly correlated with the *likert* score reported in Section 5.1. We show in Figure 2 the relation of the proportion of translations without catastrophic errors (blue bars) and the *likert* scores (red lines). As expected, systems with more translations without errors get higher *likert* scores. The Pearson's correlation coefficient for De→En (set3) is 92%, while for the other four language pairs, the coefficients are over 96%.

Distribution of error types In Figure 3 we show the absolute counts and proportion of different types of catastrophic errors per system. We note that some sentences may have been annotated with more than one error type (by different human annotators), and therefore the counts may seem inflated. To provide a better idea of the distribution of errors, for each system the error proportion is calculated as the number of translations with certain error divided by the number of sampled translations, i.e. 400. In all five language pairs, the OTH error is the main source of catastrophic errors, however, this OTH error is not clearly defined and might indicate different translation errors, e.g. some translations simply copy the source sentence and are therefore labelled as OTH error. This requires further analysis.

Excluding the OTH error (Figure 4), the catastrophic error distribution varies in different subtasks. Named entities (NAM) account for a large proportion of errors in all subtasks except En→De (set3). In En→De (set1), Ja→En (set2), and De→En (set3) subtasks, sentiment (SEN) errors are very frequent, similar to NAM errors. The TOX error is predominant only in En→Ja subtask. Other types of catastrophic errors occupy much smaller proportion.

This figure also highlights the different catastrophic error types flagged for reference translations. While this needs further inspection and investigation, we suspect that annotators might have misinterpreted the guidelines. For example, in the Wikipedia comments En→Ja, there is a large proportion of sentences with catastrophic errors of the type "toxic" (TOX): almost 10% of the reference translations contain such error type. Translations (human or machine) containing toxic content might have been tagged as containing errors, even though the source segments also contained such toxic content and the translation is simply transferring it.

Table 3: Average human judgments and catastrophic error translation rates over all submitted systems and the reference translations (p <0.05). The systems' rank for each translation direction is shown in parentheses. The best system is **highlighted**.

However, this would not explain other error types, which are defined in terms of mistranslation or mismatches between source and target content, such as incorrect named entity translation (NAM). We will analyse the data for that, as well as make it available.

6 Conclusions

The second edition of this WMT shared task focused on testing MT systems in more challenging conditions than last year, in two ways: (i) by making this in a zero-shot setting, where no training set and no in-domain development set were provided, (ii) by biasing the selection of the test sets to make them even harder to translate, for example, by oversampling segments with toxic content. We hoped to encourage participants in the other WMT translation tasks to submit to this task.

Indeed, most participating teams submitted standard NMT models trained on other types of data and other WMT tasks. Very few teams introduced specific techniques for robustness, such as augmenting training data with synthetic noise. Perhaps not entirely surprisingly, strong online systems, which are trained on a large variety of text types and domains, performed well according to both automatic and human evaluation. The only few-shot submission, however, managed to outperform online systems in most test sets, even in those from a different domain from the small training set provided. This is an interesting outcome and shows that few-shot settings are promising.

A new protocol was used for human evaluation: for general quality, direct assessment was replaced by *likert* scores with more detailed guidelines. The ranking of systems according to this human evaluation does not always agree with that given by BLEU, which is not surprising. According to human evaluation, systems were ranked together more often.

In addition to general quality, we also introduced a flag for catastrophic errors, which is a novel way to evaluate translations. The proportion of sentences containing such errors seems a lot higher than expected. This could be an artefact of the perception of human annotators on what constitutes a catastrophic error. This would explain why even the reference translations are found to contain such errors, albeit on a much smaller scale. In future work we will carry out in depth analysis on the annotation to investigate this high number of catastrophic errors in human and machine translations.

Abstract

We describe the University of Edinburgh's submissions to the WMT20 news translation shared task for the low resource language pair English-Tamil and the mid-resource language pair English-Inuktitut. We use the neural machine translation transformer architecture for all submissions and explore a variety of techniques to improve translation quality to compensate for the lack of parallel training data. For the very low-resource English-Tamil, this involves exploring pretraining, using both language model objectives and translation using an unrelated high-resource language pair (German-English), and iterative backtranslation. For English-Inuktitut, we explore the use of multilingual systems, which, despite not being part of the primary submission, would have achieved the best results on the test set.

1 Introduction

The University of Edinburgh participated in the WMT20 news translation shared task for English-Tamil and English-Inuktitut in both translation directions.[1,2] Neither language pair benefits from large quantities of parallel data, so we approach training using different techniques to compensate for this lack of data: pretraining and iterative backtranslation for English-Tamil and multilingual systems for English-Inuktitut. We use neural machine translation (MT) and specifically the transformer architecture (Vaswani et al., 2017): the base variant for the lower-resourced English-Tamil and the big variant for the mid-resource English-Inuktit. In both cases, significant improvements are seen when compared to the in-house baselines tested, particularly notable for pretraining for English-Tamil.

Awaiting the results of the official human evaluation, we report the automatic evaluation scores using BLEU (Papineni et al., 2002) as implemented in sacreBLEU (Post, 2018). A summary of these results on the dev and test sets can be found in Table 1 for all UEDIN submissions. The details of our submissions can be found in Section 2 for English-Tamil and in Section 3 for English-Inuktitut.

Language direction	Dev	Test
EN→TA	12.30	8.40
TA→EN	21.00	16.60
EN→IN	27.0	8.2
IN→EN	48.8	23.0

Table 1: Summary of results for all UEDIN submissions according to the automatic evaluation (BLEU).

2 English↔Tamil

As for our English↔Gujarati systems last year at WMT19 (Bawden et al., 2019), we use pretraining and data augmentation to tackle the low-resource language pair English–Tamil. Our experiments show that pre-training, training on backtranslated data and then fine-tuning is useful in both directions, although we introduce slight variations in the training and fine-tuning approaches used for each language direction.

2.1 Data and pre-processing

Our models are trained in the constrained scenario, using publicly available WMT20 data. We choose to exclude the terminology-like Wikititles as well as WikiMatrix[3] from our training data, using only

[1]The UEDIN participation for English-German is in a separate submission.

[2]Code and models can be found at http://data.statmt.org/wmt20_systems/.

[3]While term lists contain useful vocabulary, they can inundate the training data due to their large size. This can cause translation problems due to the different nature of the text, notably in terms of sentence length. The EN-TA portion of WikiMatrix corpus is very noisy adn so this is excluded too.

Proceedings of the 5th Conference on Machine Translation (WMT), pages 92–99
Online, November 19–20, 2020.

Data type	#sentences	Corpora
Parallel en–ta	340,995	PMindia, Tanzil, NLCP, PIB, MKB, EnTam
Monolingual en (in-domain)	653,606,835	News (crawl, discussions, commentary)

Monolingual ta (in-domain)	668,008	News crawl
Monolingual ta (out-of-domain)	1,553,160	Wiki dumps
Parallel de–en	43,675,462	Europarl, News commentary, Paracrawl, WikiMatrix, Tilde Rapid

Table 2: Data used for the Tamil-English models. Note that we also use German-English data for some of our experiments as a form of pretraining.

the corpora shown in Table 2. We use both parallel data and monolingual data for English-Tamil and also exploit parallel data available for English-German as a form of pre-training.

All data was first cleaned, keeping sentences of 3–100 (untokenised) units, for which the length ratio between the parallel sentences is maximum 2.2, and do not contain more than 50% non-alphabetic characters or more than 50% of words without an alphabetic character.[4] We deduplicate the data and normalise punctuation using Moses (Koehn et al., 2007). We then apply subword segmentation using SentencePiece (Kudo and Richardson, 2018) and the BPE strategy (Sennrich et al., 2016).[5]

2.2 Approach used

We adopt a three-step approach to training our models, consisting of: (i) *pre-training* model parameters using either an mBART language model or a translation model for the highly resourced De-En language pair, (ii) *iterative backtranslation* to produce synthetic parallel data of increasing quality, and (iii) *final model creation* consisting of fine-tuning pretrained models using both genuine parallel and backtranslated data. We provide the details of these three steps below.

Pre-training We experimented with several pre-training objectives: language modelling using XLM (Lample and Conneau, 2019a) or mBART (Liu et al., 2020), and MT pre-training using a higher-resourced language pair (namely English-German). Using a higher-resourced language pair for pretraining, even if this pair is unrelated to the language pair on which the model is fine-tuned, has shown to be an effective and simple way of boosting performance (Kocmi and Bojar, 2018; Aji et al., 2020). For the De-En models, we had to choose between (i) initialising only model parameters and (ii) preserving all model and training parameters from the parent model (similar to Grundkiewicz et al. (2019)). We chose the first option as it produced better results in our experiments.

For mBART pretraining, we use all Tamil and English monolingual data without shuffling or deduplication. We tag the input segments with a language tag and a domain tag: either in-domain (news) or out-of-domain as in (Caswell et al., 2019). For XLM pretraining we use the deduplicated and shuffled corpus (since cross-sentence context is not needed) and we subsample the English because of computing cost. We also use domain tags, with language information provided in the form of language embeddings as per the standard implementation. For De-En pre-training, we use all De-En parallel data described in Table 2, with a joint English-Tamil-German vocabulary. We experiment with pretraining models in the two directions (De→En and En→De) and find that the De→En model produces better results when fine-tuned on TA-EN data.

System	EN→TA		TA→EN	
	dev	test	dev	test
Parallel-only baseline	5.10	3.10	10.10	10.60
XLM	7.44	5.00	13.44	10.90
mBART	7.40	4.65	14.00	13.40
De-En	7.30	5.00	13.60	14.20

Table 3: Comparison of pre-training methods for EN↔TA (BLEU) after fine-tuning on parallel data.

Table 3 shows the results of each of the pretraining methods once they have been fine-tuned on Ta-En parallel data: the results are very similar and all methods perform substantially better than the baseline, which is trained on parallel data only

[4] An alphabetic character is one belonging to the language in question: the Latin alphabet for English and the Tamil script, which is an abugida script.

[5] All models are learnt jointly over the languages used for training (English, Tamil and in one case German too). The vocabulary size is dependent on the model trained and is specified in the experimental details below.

but optimised in terms of training parameters and subword segmentation. We choose to use De-En pretraining for our final models and a mixture of De-En and mBART pretraining for intermediate MT models used for data augmentation (see the next paragraph).

Iterative backtranslation Data augmentation by backtranslating monolingual data has long been used in MT to provide greater amounts of in-domain parallel data in low resource settings (Bertoldi and Federico, 2009; Bojar and Tamchyna, 2011). We use backtranslation to translate the monolingual in-domain English and Tamil texts into the other language using an intermediate MT model and use the resulting synthetic parallel data to train new MT models.

We apply this iteratively (Hoang et al., 2018), as shown in Figure 1, to produce successively better MT models, initialising the models at each stage using either mBART or De-En pretraining. The intermediate MT models used to produce backtranslations are in white and the final models, which are then fine-tuned (as specified in the section entitled *Final model creation*) are in grey.

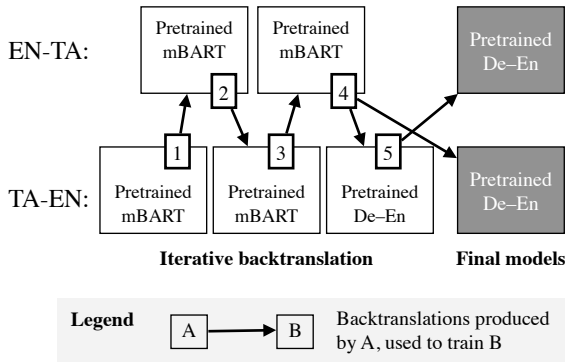

Figure 1: Iterative backtranslation process

1. We first train a Ta→En model initialised with mBART pretraining and fine-tuned on parallel data only. We then use this model to backtranslate all monolingual Tamil data into English.

2. We use the resulting backtranslated data together with the genuine parallel data to train an mBART-pretrained En→Ta model. After early stopping, we continue training using the genuine parallel data only. We then use this model to backtranslate 5M sentences of in-domain English data into Tamil.[6]

3. We use this new backtranslated data together with the genuine parallel data oversampled 7 times to train a second mBART-pretrained Ta→En model. After early stopping, we continue training using genuine parallel data only. We then use this model to backtranslate all the monolingual Tamil data.

4. We repeat step 2 with this latest backtranslated data, generating the final backtranslations to be used for the Ta→En direction.

5. We use 5M of these final backtranslations along with the Ta-En genuine parallel data oversampled 15 times to fine-tune a De-En pretrained model and use this to generate the final backtranslations to be used for the En→Ta direction.

The results of the iterative backtranslation steps on the dev set can be found in Table 4. They show increasing BLEU scores at each successive step.

System	Pretraining	BT dataset	EN→TA dev	EN→TA test	TA→EN dev	TA→EN test
1	mBART	-	-	-	14.00	13.40
2	mBART	1	10.50	5.68	-	-
3	mBART	2	-	-	18.60	**15.19**
4	mBART	3	**11.30**	**6.65**	-	-
5	De-En	4	-	-	**19.30**	-

Table 4: Results (BLEU scores) for the successive models used for backtranslations (BT) (as shown in Figure 1). Each row uses backtranslations produced by the system from the previous row.

System	EN→TA
Parallel-only baseline	5.10
(i) mBART pretraining	7.40
XLM BT	9.90
mBART BT	10.50
De-En BT	10.40
(ii) De-En pretraining	7.30
XLM BT	9.30

Table 5: Dev set results (BLEU scores) for alternative backtranslation schemes for system 2 from Figure 1.

In addition to the described strategy, we also experimented with training different pretrained models using backtranslations produced by different

[6]The En→Ta backtranslations at this step and the following steps are filtered using the same processing as described in Section 2.1, filtered using dual conditional cross-entropy filtering (Junczys-Dowmunt, 2018) and the top sentences are selected to train the next step.

models (e.g. training an mBart pretrained model on XLM-produced backtranslations). We report a small selection of these experiments here for one of the backtranslation steps, comparing the use of alternatives to system 2 (from Figure 1). These results are shown in Table 5: (i) a pretrained mBART model trained on backtranslations from each of the pretrained models, and (ii) a pretrained De-En model trained on XLM backtranslations. For this particular step of the iterative process, training a pretrained mBART model on backtranslations produced by the pretrained mBART model produced the best scores, explaining why this was chosen.

Final model creation Our final models are pretrained De-En models (in grey in Figure 1). After pretraining, the finalisation of these models follows a two-step training strategy to incorporate the synthetic and genuine parallel data:

1. We first train our models on the synthetic data described previously (20M sentences for Ta→En and just over 2.1M sentences for En→Ta).

2. We then fine-tune the models on a mixture of parallel and synthetic data.

This approach of pre-training on synthetic data and fine-tuning on genuine and synthetic data has been found to work well for other tasks (Junczys-Dowmunt and Grundkiewicz, 2016; Grundkiewicz et al., 2019). For the second step, we adopt different strategies for each language direction, depending on which worked best. For Ta→En, we fine-tune on genuine parallel data and 500k of the top scored backtranslations.[7] For En→Ta we fine-tune on a mixture of genuine parallel data, synthetic data produced using multi-agent dual learning (MADL; Wang et al., 2019; Kim et al., 2019) and the top 1M backtranslations. This MADL data comprises a mixture of forward translations and backtranslations of the parallel data created using intermediate models in both directions.

We also carried out preliminary experiments with multilingual training using other Indian languages and experiments with phrase-based MT using Moses (Koehn et al., 2007) but they did not achieve good results.

[7]Scoring is done using dual conditional cross-entropy filtering as specified in Footnote 6.

2.3 Experimental settings

We use the Marian toolkit (Junczys-Dowmunt et al., 2018) for all models except for those using XLM pretraining, for which we use the Facebook XLM toolkit (Lample and Conneau, 2019b). All models trained (including those used to produce backtranslations) use the Transformer-base architecture (Vaswani et al., 2017) with default hyperparameters according to the Marian or XLM implementation (6 encoder and 6 decoder layers, embedding dimension of 512, 16 heads, feedforward dimension of 2,048, standard learning rate warm-up).

Parallel-only baseline Our parallel-only baseline is trained with a joint vocabulary of size 5,414 for Ta-En and 418 for En-Ta. The En-Ta model was trained with a small batch size of 1000 tokens. mBart and XLM models are trained with a joint vocabulary size of 20,000 SentencePiece BPE subwords (including special tokens for language and domain tags, masking and sentence separators).

mBART training English and Tamil sentences are mixed in equal amounts in each batch. We use our re-implementation of mBART using Marian.[8] We deviate from the original implementation by always using two sentences per input segment, whereas the original paper used as many sentences as they could fit into the 512-token limit. The noise hyperparameters are the same as the original paper (35% of tokens are masked in contiguous spans of an average of 3.5 tokens. Masked spans do not cross sentence boundaries). Unlike XLM, we do not use online backtranslation during pre-training. We train until early stopping based on an held-out non-parallel dataset generated using the same noise function as the training data. During monolingual pretraining we early stop after the validation score (measured every 5,000 updates) does not improve for 10 consecutive times. When training on backtranslations or finetuning on parallel data we early stop on the parallel development corpus, measuring the valdation score every 500 updates.

De-En pretraining For models with De-En pretraining, we trained a SentencePiece model with a vocabulary size of 32k on roughly equal amounts of Tamil, English and German data (subsampling Ger-

[8]We implement an online "training harness" that reads monolingual sentences in English and Tamil, converts them to mBART training examples by applying noise and sends them to the Marian training process. Code and training scripts: https://github.com/Avmb/marian-mBART

man and English). The final MT vocabulary size is 49,213 as it is based on using all German-English data for training. The models are trained using tied target embeddings, a learning rate of 0.0002, the Adam optimiser (Kingma and Ba, 2015) and optimiser delay of 2 on 4 GPUs. We train all models until convergence based on the BLEU score on the held-out dev set provided for the task.

2.4 Results

Table 6 shows the final automatic evaluation score of our submissions for both directions on the dev set and the test set, including an ablation of the various components: pretraining using the De-En MT data (and fine-tuned on parallel data), addition of synthetic data to this setup and finally fine-tuning of the resulting model as specified previously.

System	EN→TA		TA→EN	
	dev	test	dev	test
Parallel-only baseline	5.10	3.10	10.10	10.60
Our final models				
Pretraining (De-En)	7.30	5.00	13.60	14.20
+ synthetic data	11.90	7.90	18.80	12.60
+ fine-tuning	**12.30**	**8.40**	**21.00**	**16.60**

Table 6: EN↔TA results (BLEU scores) for the successive steps in the creatino of our final models. The Last row represents the primary submission systems.

The best results (8.40 for En-Ta and 16.60 for Ta-En) are achieved with all three approaches to training. We found that ensembling did not improve our results and therefore our submitted systems are single models. We note that our final approach sees a big difference in the BLEU score between the dev and test sets. While BLEU scores are not directly comparable across datasets, the drop is quite significant and could indicate a domain shift between the two sets. Our models rely heavily on the use of backtranslated data and therefore could be adapting to translationese, which is rewarded in the dev set but not in the test set.

3 English↔Inuktitut

Compared to English-Tamil, the English-Inuktitut language pair is relatively well-resourced at approximately 1.3M sentence pairs. As such we were able to train conventional bilingual Transformer systems, which formed the basis of our submission. We also trained multilingual systems, but opted not to use these in our submission as results on the dev set did not appear to be promising (although evaluation proved challenging for this pair due to overlap between the training and dev data). Post-submission evaluation showed that our multilingual systems actually outperformed our submitted systems on the test sets.

3.1 Data and Preprocessing

We used all of the Nunavut Hansard data provided by the task organisers. For Inuktitut→English, this was supplemented with a similar volume of synthetic data, back-translated from the English side of the Europarl and News Crawl corpora. The only additional monolingual Inuktitut data was 163k sentences of common-crawl data, which we back-translated for the English→Inuktitut system.

We developed two multilingual systems: English→ {Inuktitut,German,Russian} and {Inuktitut,German,Russian} → English. The Russian and German languages were selected due to the availability of suitable volumes of data in the domains of interest (news and parliamentary proceedings). Both multilingual systems used the same dataset, which contains genuine iu-en, synthetic iu-en, genuine de-en, and genuine ru-en in a ratio of approximately 1:1:2:2 (both systems used all of the synthetic data, regardless of back-translation direction). Table 7 lists all of the corpora used for the multilingual systems

Lang. Pair	Size	Corpus
en-iu	1,310k	Nunavut Hansard
en-iu	650k	Synthetic (from en Europarl)
en-iu	650k	Synthetic (from en News 2019)
en-iu	163k	Synthetic (from iu CommonCrawl)
en-de	361k	News Commentary
en-de	1,817k	Europarl
en-de	400k	Paracrawl
en-ru	1,000k	Yandex
en-ru	1,600k	UN

Table 7: Data used for the multilingual English-Inuktitut models. Size is given in sentence pairs.

For the bilingual systems, our preprocessing pipeline consisted of corpus cleaning and segmentation. For corpus cleaning, we used the `clean-corpus-n.perl` script from the Moses toolkit (Koehn et al., 2007). This applies a maximum length threshold of 80 as well as removing empty sentences and sentence pairs with length ratios greater than 9:1.

For segmentation, we trained language-specific SentencePiece models (Kudo and Richardson, 2018) with a vocabulary size of 32,000 BPE subwords and a vocabulary threshold of 50.

Preprocessing was identical for the multilingual systems except that for the English→ {de,iu,ru} we added a token to each source sentence to specify the target language (as in Johnson et al. (2017)).

After the release of the test set, the task organisers reported that some test sentences had been enclosed in extraneous quotes. For our submission, and for post-submission evaluation, we removed outer quotes prior to translation for any test sentence that began and ended with a double quote character.

3.2 Experimental Settings

We used the Nematus toolkit (Sennrich et al., 2017) for all models. For preliminary systems, our hyperparameter settings matched the 'base' configuration of Vaswani et al. (2017). We used these systems for back-translation. For the multilingual systems and final bilingual systems, our settings matched Vaswani et al. (2017)'s 'big' configuration. We used a batch size of 16,384 tokens for all models.

Since the bilingual 'big' systems looked the most promising during development, we trained a second model for each direction and used ensembling in our submission systems.

3.3 Results

Table 8 shows the automatic evaluation scores for our submitted ensemble systems as well as individual bilingual systems and multilingual systems.

Post-submission evaluation on the test set shows that the multilingual systems outperformed the bilingual systems, which is in contrast to the results obtained on the dev sets during system development. We suspect that the large differences in BLEU between dev/test and bilingual/multilingual to overlap between the Nunavut training and dev data. We found that a large proportion of dev sentences were present in the training data, although many were short, frequently used phrases, such as 'Thank you, Mr. Speaker.' and 'The motion is carried.' During development we tried filtering the dev set to reduce overlap at the sentence level. This lowered the scores, but still produced the same overall order: bilingual big > bilingual base > multilingual and so we used this result to guide our decision on which systems to submit. With hindsight, we suspect that the prevalence of formulaic, but not necessarily identical, constructions in the text may be a complicating factor and that more aggressive filtering of the dev set may have produced more robust results. Compared to the bilingual base or multilingual models, the bilingual big models have more capacity available for memorisation of the training data and it seems that our filtering was not enough to counter this effect.

4 Conclusion

In this submission we focused on a low-resource language pair (English-Tamil) and a medium-resource language pair (English-Inuktitut). All our translation systems are based on the Transformer architecture. We found it beneficial to use monolingual data in the form of backtranslations. In the case of En-Ta, we saw notable gains by using pretraining using both the denoising autoencoding (mBART) objective and multilinguality in the form of German-English pretraining. However, we were not able to gain any quality from multilingual training on data for other Indian languages. For English-Inuktit, multilinguality did not appear to help on the dev set, but was found, post-submission, to help on the test set.

In general, we found that English-Tamil is a much more challenging task, where pretraining is absolutely necessary to reach acceptable quality, while for English-Inuktit reasonable translation quality can be achieved using only parallel data.

GTCOM Neural Machine Translation Systems for WMT20

Chao Bei, Hao Zong, Qinming Liu and Conghu Yuan
Global Tone Communication Technology Co., Ltd.
{beichao, zonghao, liuqingmin and yuanconghu}@gtcom.com.cn

Abstract

This paper describes the Global Tone Communication Co., Ltd.'s submission of the WMT20 shared news translation task. We participate in four directions: English to (Khmer and Pashto) and (Khmer and Pashto) to English. Further, we get the best BLEU scores in the directions of English to Pashto, Pashto to English and Khmer to English (13.1, 23.1 and 25.5 respectively) among all the participants. Our submitted systems are unconstrained and focus on mBART (Multilingual Bidirectional and Auto-Regressive Transformers), back-translation and forward-translation. Also, we apply rules, language model and RoBERTa model to filter monolingual, parallel sentences and synthetic sentences. Besides, we validate the difference of the vocabulary built from monolingual data and parallel data.

1 Introduction

We participated in the WMT shared news translation task and focus on the bidirections: English and Khmer, English and Pashto. We applied fairseq(Ott et al., 2019) as our develop tool and use transformer(Vaswani et al., 2017) as the main architecture. The primary ranking index for submitted systems is BLEU (Papineni et al., 2002), therefore we apply BLEU as the evaluation matrix for our translation system. For Khmer, we use polyglot [1] as the tokenizer before evaluation.

For data preprocessing, the basic method includes punctuation normalization for all language. Further, according to the different language characteristics. Tokenization, truecase and byte pair encoding (BPE) (Sennrich et al., 2015b) are applied for English, and sentencepiece (Kudo and Richardson, 2018) is applied for Khmer and Pashto. Besides, human rules, language model and RoBERTa model (Liu et al., 2019) are also involved to clean parallel data, monolingual data and synthetic data. Regard to the techniques on model training, back-translation (Sennrich et al., 2015a) and forward-translation are applied to verify whether these techniques could improve the translation performance especially in low-resource condition.

We all know that it is more difficult to train a model in low-resource condition, because it suffers from data sparsity and out-of-vocabulary problem. Normally knowledge distillation (Kim and Rush, 2016) is a good way to generate synthetic data. But in this task we suppose that knowledge distillation can only generate 100 thousand to 1 million parallel sentences due to the size of provided data. Therefore, we use forward-translation with monolingual data to generate more synthetic data. Here forword-translation refers to translate the source sentences to target language, and clean synthetic data.

This paper is arranged as follows. We firstly describe the task and show the data information, then introduce how we do data filtering, including human rules, language model and RoBERTa model. After that, we describe the techniques on low-resource condition and show the conducted experiments in detail of all directions, including data preprocessing, model architecture, back-translation and forwor-translation. At last, we analyze the results of experiments and draw the conclusion.

2 Task Description

The task focuses on bilingual text translation in news domain and the provided data is show in Table 1, including parallel data and monolingual data. For the direction between English and Khmer, the parallel data is mainly from ParaCrawl v5.1 and shared task on parallel corpus filtering (mostly from OPUS (Tiedemann, 2012)), as well as the direction between English and Pashto. Another, monolin-

gual data we used are News crawl both for English, Common Crawl and Wiki dumps both for Khmer and Pashto. All directions we participated are new for this year, we use wikipediadev as our development set and wikipediadevtest as our test set.

3 Data Filtering

The methods of data filtering are mainly the same as we did in last year (Bei et al., 2019), including human rules and language model. Further, another methods we used this year are as follows:

Clean repeated translation sentences in synthetic data. For example, we often see the translation like: I want to eat an apple apple apple apple apple, when translating a source language sentence with repeated words until the end of the sentence. In this task, we made a simple clean strategy which is to remove the sentences that repeat one word four times, two words three times or three words two times.

Clean synthetic data by RoBERTa model. In order to clean synthetic data, especially from forword-translation, we represent the source and target sentences by RoBERTa model and calculate the cosine distance. Remove the sentences with low score or without translation (the source sentence and target sentence are same).

4 Forward-translation

In low-resource condition, out-of-vocabulary is a problem. There is a difference between the test scenario and training scenario, which means the words appear in test set may be not existed in training vocabulary. Back-translation is a common way to extend the word vocabulary. However, with the generated synthetic data from back-translation, only target vocabulary can be enriched. To extend the source side vocabulary, we use source-to-target model to translate the source monolingual data to target side. Further, it is necessary to clean the forward-translation sentences to avoid cascading error for the next training. We use RoBERTa to represent the source and target sentence and calculate the cosine distance. Remove the sentences with low score or without translation (the source sentence and target sentence are same).

5 Experiment

5.1 Model architecture

- **Baseline** Table 2 shows the baseline model architecture.
- **mBART** We fine-tune on mBart model to get better translation. Table 3 shows the model architecture.
- **Big transformer** We use transformer big model to train our model with fairseq. The model configuration and training parameters is almost same as last year we use. In order to training more stable in low-resource condition, we add layer normalize before encoder and decoder.

5.2 Training Step

This section introduces all the experiments we set step by step and Figure 1 shows the whole flow.

- **Date Filtering** Following the task of Parallel Corpus Filtering and Alignment for Low-Resource Conditions, we use the LASER-based scores to filter the raw parallel sentences and extract 5 million words England tokens.
- **Baseline.** We use FLoRes (Guzmán et al., 2019) architecture to construct our baseline in low-resource condition.
- **Fine-tuning on mBART.** In such low-resource condition, we fine-tune on mBART model with filtered sentences.
- **Back-translation.** We use fine-tuned model to translate the target sentence to source side, and clean synthetic data with language model and RoBERTa model. Mix cleaned back-translation data and parallel sentences and fine-tune on mBART model.
- **Forward-translation.** Source side sentences are translated to target side, and cleaned by language model and RoBERTa model. Mixed with cleaned back-translation data, forward-translation data and parallel sentences, fine-tune on mBART model.
- **Monolingual vocabulary.** To enrich the vocabulary further, we preprocess the monolingual data and build the vocabulary as model vocabulary. Here, we normalize the punctuation of all data by nomalize-puncuation.perl in Moses toolkit (Koehn et al., 2007). We apply tokenizer and truecaser in Moses toolkit for English. Finally, BPE (Byte Pair Encoding) (Sennrich et al., 2016) is applied on tokenized English and sentencepiece is applied on Pashto and Khmer. The BPE and sentencepiece merge operation are both 32000. Therefore, the vocabulary of monolingual data is set to 32500. We use these vocabularies as model vocabulary and train big transformer model.
- **Joint training.** Repeat back-translation step and forward-translation step by best model, until there is no improvement.
- **Ensemble Decoding.** We use GMSE Algorithm (Deng et al., 2018) to select models to obtain the best performance.

6 Result and analysis

Table 4 and Table 5 show the BLEU score we evaluated on development set for English to Pashto, Pashto to English, English to Khmer and Khmer to English respectively.

For fine-tuning on mBART model, we find that it is the most effective method with an improvement from 0.56 to 3.62 BLEU score in low-resource condition. And back-translation gets the improvement from 0.17 to 3.04 BLEU score. Forward translation and monolingual vocabulary enrich the information in low-resource condition, with improvement of 0.16 to 0.74 BLEU score and 0.69 to 0.94 BLEU score respectively. Further, joint training and ensemble decoding slightly increase the performance with 0.31 to 0.4 BLEU score and 0.15 to 0.4 BLEU score.

7 Summary

This paper describes GTCOM's neural machine translation systems for the WMT20 shared news translation task. For all translation directions, we build systems mainly base on mBART model and enrich information by back-translation, forward-translation and using monolingual vocabulary with data filtering, including calculating cosin distance by RoBERTa model, language model and so on. The effect of increasing information is also dependent on data filtering. Finally, we submit the online system including English to Pashto, Pashto to English, Khmer to English and English to Khmer with almost same methods in this paper. Another, we also submit our online system from English to Tamil and Tamil to English.

Abstract

This paper describes DiDi AI Labs' submission to the WMT2020 news translation shared task. We participate in the translation direction of Chinese→English. In this direction, we use the Transformer as our baseline model, and integrate several techniques for model enhancement, including data filtering, data selection, back-translation, fine-tuning, model ensembling, and re-ranking. As a result, our submission achieves a BLEU score of 36.6 in Chinese→English.

1 Introduction

We participate in the WMT2020 news translation shared tasks in Chinese → English direction. For this translation direction, we train several variants of Transformer (Vaswani et al., 2017) models on the provided parallel data enlarged with synthetic data from monolingual data. We experiment with several techniques proposed in the past translation tasks and adopt effective ones as components of our system.

Our data preparation pipeline consists of data filtering, data augmentation, and data selection. For data filtering, we filter sentence pairs based on language model scoring, alignment model scoring, etc. For data augmentation, we experiment with iterative back-translation (Sennrich et al., 2016; Edunov et al., 2018) methods and iterative knowledge distillation (Freitag et al., 2017) methods. We leverage source-side monolingual data by applying iterative knowledge distillation, and target-side monolingual data by back-translation methods, including greedy search, beam search, and noised beam search. For data selection, we select an in-domain corpus with N-grams language models and binary classifiers. A tri-gram token-level language model and a bi-gram character-level language model are introduced for English and Chinese respectively. Out-of-domain sentences which have similar scores as in-domain sentences are chosen. We also treat data selection as a text classification problem, and use BERT (Devlin et al., 2019) as the basic classifier. In this way, we collect a corpus of high-quality in-domain training data, which improves translation performance significantly.

To enhance a single model, we use several variants of Transformer, including Transformer with relative position attention (Shaw et al., 2018), Transformer with larger feedforward inner (FFN) size ($8,192$ or $15,000$), and Transformer with reversed source. We then ensemble these models with adequate model diversity and data diversity to further improve the performance.

Domain conflicts influence the translation performance significantly. For example, there exist differences between written English and spoken English. Usually, a model cannot do the best in all domains due to the conflicts. In this work, we propose to obtain domain information with unsupervised clustering and exploit this information for translation. Specifically, we partition the training data, dev data, and test data into different clusters, and translate each cluster part of the test set with the model fine-tuned on the corresponding training set. Exploiting domain information helps improve the translation significantly. Details will be discussed in Section 3.

This paper is structured as follows: Section 2 describes variants of Transformer we used in the competition. In Section 3, we introduce several techniques for model enhancement, including data filtering, back-translation, fine-tuning, model ensembling. Section 4 presents experimental settings, results and analysis. Finally, in Section 5 we draw a brief conclusion of our work in the WMT2020.

Proceedings of the 5th Conference on Machine Translation (WMT), pages 105–112
Online, November 19–20, 2020.

2 Model

2.1 Transformer

The Transformer adopts a sequence-to-sequence structure, using stacked encoder and decoder layers of self-attention. Encoder layers consist of a self-attention layer followed by a feed-forward layer. Decoder layers consist of a masked self-attention layer, an encoder-decoder attention layer, and a feed-forward layer to incorporate source information and generate texts. The residual connections (He et al., 2016) and layer normalization (Ba et al., 2016) are introduced in the encoder and decoder layers for better convergence. In contrast to recurrent neural networks, the Transformer implicitly leverages relative and absolute position information in its structure. The Transformer introduces position encoding based on sinusoids in its inputs to incorporate position information.

In the competition we use Transformer Big as the baseline model, in which both the encoder and decoder have 6 layers, the number of heads is 16, the hidden size is $1,024$, and the feedforward inner (FFN) size is $4,096$.

2.2 Transformer with Relative Position Attention

The original Transformer leverages position information by taking absolute positional embeddings as inputs and does not explicitly capture the information in its structure. Thus the original Transformer cannot leverage position information efficiently. Here we used relative positional embeddings in the self-attention mechanism proposed in Shaw et al. (2018) for the encoder layers and decoder layers. We do an ablation study and find that the model with relative positional embedding has faster convergence and better performance than Transformer Big. We adopt Transformer with relative position attention as a basic architecture in the final ensemble model.

2.3 Transformer with Larger FFN Size

Since increasing the model size can help improve the performance on the NMT tasks, we experiment with Transformer with a larger embedding dimension, FFN size, number of heads, and number of layers. We find that using a larger FFN size ($8,192$ or $15,000$) gives a reasonable improvement in the performance while maintaining a manageable network size. We adopt a Transformer with FFN size of $8,192$ and a Transformer with FFN size of $15,000$ as basic models in the final ensemble model, which has a larger inner dimension of feed-forward network than Transformer Big. Since Transformer with a larger FFN size is more likely to overfit, we set the dropout rate from 0.1 to 0.3 and use a label smoothing rate of 0.2.

2.4 Transformer with Reversed Source

We reverse the source sentences of the bilingual corpus and train a Transformer with source reversed. In this way, the model can learns a different meaning of the positional embeddings, which helps capture the source sentences from a different perspective. Viewing source in a reversed order provides another kind of model diversity and data diversity and presents positive effects in the final model ensemble.

3 System Overiew

3.1 Data Filtering

Previous works (Sun et al., 2019; Xia et al., 2019; Guo et al., 2019) show that the translation performance improves as the quality of parallel corpus improves. We filter the training bilingual corpus with the following schemes:

- Normalize punctuation with Moses scripts
- Filter out the sentences longer than 120 words or sentences including a single word more than 40 characters.
- Filter out the sentences which contain HTML tags or duplicated translations.
- Filter out the sentences whose languages detected by fastText[1] (Joulin et al., 2017) are not identical to the translation direction.
- Filter out the sentences whose alignment scores obtained by fast-align[2] (Dyer et al., 2013) are low.
- Filter out the sentences whose n-gram scores from language models are low.
- Filter out the sentences whose length ratio between the source and target are not in range of $1:3$ and $3:1$

[1] https://github.com/facebookresearch/fastText
[2] https://github.com/clab/fast_align

In this paper, we also filter out noisy sentence pairs with the translation acceptability filter proposed in (Zhang et al., 2020). Specifically, we feed the sentence pair (s, t) into multilingual BERT, which accepts two-sentence input due to its next-sentence prediction objective. Instead of using the [CLS] token representation, we use a Convolutional Neural Network (CNN) layer that takes the BERT output and generates the final representation of the pair. Our experiments show that using CNN layer pooling achieves marginal gains over [CLS] pooling. We use the softmax probability as the degree of parallelism and filter the sentences. The translation quality of the model boosts with the data filtering strategies.

3.2 Large-scale Back-Translation

The provided monolingual data contains a certain amount of noise, in which noise may affect the translation quality implicitly. Therefore, we adopt the data filtering schemes described in Section 3.1.

Previous work (Edunov et al., 2018) shows that leveraging the back-translation mechanism on the large-scale monolingual corpus can help improve the translation quality. Edunov et al. (2018) investigates several methods to generate synthetic source sentences, including greedy search, beam search, sampling top-K outputs, adding noise to beam search output, and adding noise to input sentences.

- Both greedy search and beam search are approximate algorithms to identify the maximum a-posteriori (MAP) output, i.e. the sentence candidate with the largest estimated probability given an input. This leads to less rich translations and is particularly problematic for text generation tasks such as back-translation.

- Sampling top-K method selects the k most likely tokens from the output distribution, renormalizes, and samples from this restricted set. This method is a trade-off between MAP and unrestricted sampling.

- Adding noise to input sentences or beam search outputs can help improve the quality and robustness of the translation.

We experiment with the above methods and observe that language pairs with abundant parallel corpus like Chinese → English obtain obvious improvement with beam search and adding noise. In our back-translation scheme, we add noise to input sentences, and use a beam search to produce the synthetic sentences. In particular, we delete words, replace words by a filler token and swap words according to a random permutation with the probability of 0.05.

Zhang et al. (2018) proposed an iterative joint training of the source-to-target model and target-to-source model for the better quality of synthetic data. Specifically, in each iteration, the target-to-source model is responsible for generating synthetic parallel training data for the source-to-target model using the target-side monolingual data. At the same time, the source-to-target model is employed for generating synthetic bilingual training data for the target-to-source model using the source-side monolingual data. The performance of both the target-to-source and source-to-target model can be further improved iteratively. We stop the iteration when we can not achieve further improvement.

Since there are amounts of genres in both parallel and synthetic data, we adopt a language model to divide data into a coarse domain-specific corpus. We train multiple language models on different types of monolingual data (News crawl, Gigaword, etc.), and score the sentences with the language models. We select the top 600K sentences for each domain. In the final submission, we adopt an iterative joint training scheme and train models on both bilingual and synthetic data of different genres to improve translation quality.

3.3 Knowledge Distillation

Alternate knowledge distillation (Hinton et al., 2015; Freitag et al., 2017) and ensemble iteratively is adopted in the competition to further boost the performance of a single model. We simply use an ensemble model as the teacher model and boost the single student model by data augmentation. In our experiments, we use Transformer Big, Transformer with relative position, Transformer with larger FFN size, and Transformer with reversed source as basic models. For each model type, we ensemble other model types as the teacher model to boost the model performance. For example, the ensemble model of a Transformer with relative position, a Transformer with larger FFN size, and a Transformer with reversed source are adopted as a teacher model to improve the performance of a

Transformer Big.

Considering that distillation from a poor-quality teacher model is likely to hurt the student network and thus results in an inferior performance, we selectively use distillation in the training process. In our experiments, we filter out data according to the sentence-level BLEU scores whose English translations lower than 28.

3.4 In-domain Data Selection and Fine-tuning

Domain adaptation plays an important role in improving the performance towards given test data. A practical method for domain adaptation is training on the large-scale data and then fine-tuning on the in-domain data (Luong and Manning, 2015). We select the small in-domain corpus with several approaches, including N-grams language model similarity and binary classification.

N-grams: We adopt the algorithm proposed in Duh et al. (2013); Axelrod et al. (2011), which selects sentence pairs from the large out-of-domain corpus that are similar to the in-domain data. In our work, we train a tri-grams token-level language model for English and a bi-grams character-level language model for Chinese. We use the parallel texts as the out-of-domain corpus and all available test sets in the past WMT tasks and News Commentary as the in-domain corpus. We score the sentence pairs with bilingual cross-entropy differences as follows:

$$CE(H_{I-SRC}, H_{O-SRC}) + CE(H_{I-TGT}, H_{O-TGT}) \quad (1)$$

where we denote out-of-domain corpus as O, in-domain corpus as I. H_{I-SRC} denotes language models over the source side and H_{I-TGT} denotes language models over the target side on in-domain data. H_{O-SRC} denotes language models over the source side and H_{O-TGT} denotes language models over the target side on out-of-domain data. CE denotes the cross-entropy function which evaluates the differences between distributions.

Finally, we sort all sentence pairs and select the top 600K sentences with the lowest scores to fine-tuning the parameter of the model.

Binary Classification: We also treat in-domain data selection as a text categorization problem. There are two categories: in-domain (1) and out-of-domain (0). We use the pre-trained language model BERT as the basic classifier. For the fine-tuning data, all available newstest data and News Commentary are regarded as positive data, and randomly sampled data from the large-scale corpus are regarded as negative data. Then BERT is exploited to score the sentence pairs. We sort all sentence pairs and select the top 600K sentences with the highest scores as fine-tuning data.

All the in-domain data obtained by the above methods are adopted to fine-tuning the single model and provide about a 2 BLEU scores improvement.

3.5 Model Ensemble

Ensemble learning is a widely used technique in the real-world tasks, which provides performance improvement by taking advantages of multiple single models. In neural machine translation, a practical way of the model ensemble is to combine the full probability distribution over the target vocabulary of different models at each step during sequence prediction. We experiment with the max, avg, and log-avg strategies, and find the log-avg strategy achieves the best performance. We implement a model ensemble module in OpenNMT[3] (Klein et al., 2017). In our experiments, we observe that simply enlarging the size of ensemble models does not necessarily improve translation performance. However, brute-force search of all models is prohibitively expensive and unrealistic. As the number of models increases, the decoding of the ensemble will take more time than a single model and exceed the limits of computer resource capacity. Therefore, we adopt a greedy model ensemble algorithm (Li et al., 2019) as shown in Algorithm 1.

Since model and data diversity are important factors for an ensemble system, we train diverse models with different initialization seeds, different parameters, different architectures, and different training data sets. All the models are fine-tuned to achieve superior performance.

3.6 Domain Style Translation

Translation performance differs in different topic domains. For intuitive explanation, we take native style and translation style as an example, and our topic domains are generated by using unsupervised clustering, not limited to these two styles. Native style and translation style are much different. A single model cannot do the best in both styles. For the Chinese $\rightarrow$ English task in WMT 2017 and 2018, the source side of both dev set and test set

[3]https://github.com/OpenNMT/OpenNMT-tf

Input: a model list Ω_{cand} sorted by the scores on development data.
Output: a final model list Φ_{final}

```
for all combination of 2 models that model ∈ top-8 models do
    obtain translation by ensemble decoding and evaluate with BLEU score;
end
Choose the best 2 model combination as the initial Φ_final;
while there is tiny improvement as the model number increases do
    choose one single model from the rest of Ω_cand to the Φ_final which performs better when combined with Φ_final;
end
```

are composed of two parts: documents created originally in Chinese (translation style) and documents created originally in English (native style). For the Chinese→English task, if the Chinese sentences are created from native Chinese corpus, then the corresponding English sentences are in translation style, so the model fine-tuned on these parallel sentences helps with translation style. Similarly, if the English sentences are created from native English corpus, the model fine-tuned on these sentences helps with native style. Previous work (Sun et al., 2019) shows exploiting translation style and native style achieves much better performance. In our work, we classify sentences into different topic categories (not limited to translation style and native style), and translate each specific part of the test set with the model fine-tuned on the corresponding training set.

Domain Label: We use pre-trained BERT models to extract [CLS] vector as the sentence embedding and obtain two clusters by K-Means clustering. We use the cluster id as the domain label.

Domain Classification: Pre-trained BERT models are fine-tuned as a text classification task, based on the source and target side with the domain label we defined above. In this way, we can select several fine-tuning data w.r.t. different topic domains.

Decoding Stage: Since the test data is composed of a mixed-genre data, we first classify the domain of each sentence in the test set and obtain the probabilities corresponding to each domain. Then we apply a weighted ensemble method to integrate NMT models. Specifically, when computing the output probability of the next word, we multiply the output probability in each domain-specific translation model with the corresponding domain probability of each sentence.

3.7 Re-ranking

We obtain n-best hypotheses with an ensemble model and then train a re-ranker using k-best MIRA (Cherry and Foster, 2012) on the validation set. K-best MIRA works with a batch tuning to learn a re-ranker for the n-best hypotheses. The features we use for re-ranking are:

- Length Features: length ratio and length difference between the source sentences and hypotheses
- NMT Features: scores from the ensemble model
- Language Model Features: scores from multiple n-gram language models

4 Experiments and Results

4.1 Experiment Setup

Our implementation of the Transformer models is based on the version 2.3.0 of OpenNMT-tf. We use Transformer Big as a basic model. Transformer Big has 6 layers in both encoder and decoder respectively, where each layer consists of a multi-head attention sublayer with 16 heads and a feed-forward sublayer with inner dimension 4096. The word embedding dimensions and the hidden state dimensions are set to 1024 for both encoder and decoder. In the training phase, the dropout rate $P_{dropout}$ is set to 0.1. Variants of Transformer described in Section 2 are adopted in the competition.

In the training phase, we use cross entropy as the loss function and apply label smoothing of 0.1. We use Adam (Kingma and Ba, 2014) as our optimizer, with parameters settings $\beta_1 = 0.9$, $\beta_2 = 0.98$ and $\epsilon = 10^{-8}$. The initial learning rate is set to 10^{-4} for training and 10^{-5} for fine-tuning. The models are trained on 4 GPUs for about $500,000$ steps. Each model learns from data randomly sampled from the whole corpus, including bilingual data, synthetic data from back-translation, and synthetic data from knowledge distillation. Models

Table 3: Comparison with related work on the WMT 2018 and 2019 Chinese → English test set

used in iterative back-translation and knowledge distillation are trained for $200,000$ steps. We validate the model every $1,000$ steps on the development data and save the checkpoints with the best BLEU scores. After training, we average the last 10 checkpoints for every single model of the general domain.

In the fine-tuning phase, we use the averaged model obtained in the training phase as pre-train weights for domain models, and train with in-domain data selected as in Section 3.4 for $10,000$ steps without early stop. After fine-tuning, we average the last 10 checkpoints for every single model of the specific domain.

For evaluation, we adopt the cased BLEU scores calculated with SacreBLEU (Post, 2018).

4.2 Pre-processing and Post-processing

In pre-processing, we conduct data filtering, tokenization, subword encoding. For Chinese sentences, we use the DiDi tokenizer for tokenization. For English data, we do punctuation normalization and use Spacy[4] tokenizer for tokenization. We filter parallel sentences as described in Section 3.1. Finally, we collect a preprocessed bilingual training data consisting of 10M parallel sentences and 20M synthetic sentences. We adopt subword encoding for Chinese → English. Specifically, we learn a BPE with 40K merge operations, in which 37.8K and $27.8K$ subword tokens are adopted as Chinese and English vocabularies separately.

In the post-processing phase, we conduct unknown (UNK) words replacement, de-tokenization, punctuation, and numerals normalization. UNK words are simply removed in the sentences. We use the Moses scripts to true-case and de-tokenize the English translations.

4.3 Chinese → English

We adopt methods in Section 3 for Chinese → English task. Firstly we adopt techniques of iterative back-translation and knowledge distillation for generating synthetic parallel data based on monolingual data. We combine the synthetic data and bilingual data as the training data and randomly split training data into 6 portions and do experiments to obtain 3 most effective portions. We train several models with different initialization seeds, different training datasets, and different architectures with the sampled synthetic data and bilingual data. In this way, we obtain models with diversity. After that, we fine-tune the model with different in-domain data. Next, we do the model ensemble by exploiting the translation domain style and choose the best model on development data as the final submission. Here we use WMT 2018 test set and WMT 2019 test set as our development data. Finally, we adopt several re-ranking and post-processing methods to obtain the final submission.

Table 1 shows the results on WMT 2018 test data of Chinese → English. As shown in the table, data augmentation with iterative back-translation and knowledge distillation consistently improve the BLEU score. Fine-tuning with selected in-domain corpus plays an important role in our system, which helps achieve improvement about more than a 2 BLEU score. We observe that ensemble with log-

[4]https://github.com/explosion/spaCy

avg strategy achieves slight improvement, which may be caused by the conflicts between different topic domains. To alleviate domain conflicts, we incorporate the domain style information, which achieves 2.15 improvement over the best single model. We also observe a relatively slight improvement with re-ranking. The reason may be that we use the training data to train both the re-ranker and the NMT models, which produces similar scores while dealing with the same sentences. Similar conclusions can be drawn from Table 2.

Table 3 shows the BLEU comparisons with related works on the WMT 2018 and WMT 2019 test sets. From the table, we observe that our system achieves the best performance on the WMT 2018 test set and the second best performance on the WMT 2019 test set. This demonstrates the effectiveness of the proposed system.

In our final submission, the model is an ensemble of 6 models, including 2 Transformer, 1 Transformer with relative position attention, 2 Transformer with larger FFN size, and 1 Transformer with reversed source. We do translation with beam size=10 and length penalty=1.4. Finally, we achieve a cased BLEU score of 36.6 in WMT 2020 Chinese $\rightarrow$ English competition.

5 Conclusion

In this paper, we present our NMT systems for WMT2020 news translation shared tasks in Chinese $\rightarrow$ English translation direction. Our final system achieves substantial improvement over baseline systems by integrating the following techniques:

1. Data filtering
2. Data augmentation, including iterative back-translation, knowledge distillation, etc.
3. Fine-tuning with in-domain data
4. Model ensemble and leverage domain topic information

As a result, our submitted system achieves a 36.6 BLEU score in the Chinese $\rightarrow$ English direction of WMT 2020 news translation shared tasks.

Abstract

This paper describes Facebook AI's submission to WMT20 shared news translation task. We focus on the low resource setting and participate in two language pairs, Tamil ↔ English and Inuktitut ↔ English, where there are limited out-of-domain bitext and monolingual data. We approach the low resource problem using two main strategies, leveraging all available data and adapting the system to the target news domain. We explore techniques that leverage bitext and monolingual data from all languages, such as self-supervised model pretraining, multilingual models, data augmentation, and reranking. To better adapt the translation system to the test domain, we explore dataset tagging and fine-tuning on in-domain data. We observe that different techniques provide varied improvements based on the available data of the language pair. Based on the finding, we integrate these techniques into one training pipeline. For En → Ta, we explore an unconstrained setup with additional Tamil bitext and monolingual data and show that further improvement can be obtained. On the test set, our best submitted systems achieve 21.5 and 13.7 BLEU for Ta → En and En → Ta respectively, and 27.9 and 13.0 for Iu → En and En → Iu respectively.

1 Introduction

We participate in the WMT20 news translation task in two low resource language pairs (four directions), Tamil ↔ English (Ta → En and En → Ta) and Inuktitut ↔ English (Iu → En and En → Iu). These language pairs are challenging due to the lack of in-domain bitext training data and limited monolingual data. For Tamil, the available bitext corpora are from various sources; however, none of the sources is in the news domain, and each corpus is in limited size or noisy. Inuktitut encompasses the challenges present for Tamil, but is even more challenging because the quantity of available monolingual data is even less than the bitext data.

We explore techniques that leverage available data from all languages. First, we investigate supervised learning together with pre-training using mBART (Liu et al., 2020). Second, inspired by the recent success of improving low resource languages through multilingual models (Arivazhagan et al., 2019; Tang et al., 2020), we explore the utility of multilingual models, in the form of multilingual pretraining and subsequent fine-tuning. Third, we leverage the monolingual data of the source and target languages using data augmentation techniques, such as back-translation (Sennrich et al., 2015) and self-training (Ueffing, 2006; Zhang and Zong, 2016; He et al., 2019). Following Chen et al. (2019), we apply these techniques iteratively. Fourth, we use noisy-channel model reranking (Yee et al., 2019) to further boost performance. The reranking uses language modeling to select a more fluent hypothesis, which requires monolingual data in the target language.

Additionally, we investigate how adding substantially more unconstrained data can further improve the performance of En → Ta system. We incorporate data from bitext mining efforts such as CCMATRIX (Schwenk et al., 2019) and CCALIGNED (El-Kishky et al., 2019), as well as additional monolingual data from CCNET (Wenzek et al., 2019) curated from CommonCrawl. The additional data is used for iterative back-translation and to train stronger language models for noisy-channel reranking.

In a complementary direction, we investigate ways to adapt the translation system to the target domain. We explore controlled generation by adding dataset tags to indicate domain. Furthermore, we fine-tune our system on the in-domain data.

For all language directions, we obtain our final systems by fusing a combination of the tech-

Proceedings of the 5th Conference on Machine Translation (WMT), pages 113–125

niques mentioned above. We observe that the bulk of the improvements in our systems are from iterative back-translation and self-training, except the En → Iu system where we only have exceptionally limited quantities of Inuktitut monolingual data. Noisy-channel reranking provides further improvement on top of strong systems, especially for to-English directions where we have high-quality news-domain monolingual data to train a good language model. Each of the other techniques, including dataset tagging, fine-tuning on in-domain data, and ensembling also provides nice improvements.

2 Data

For the constrained track, we use monolingual data from all languages provided in WMT20 for mBART pre-training (Liu et al., 2020), and we use bitext data between English and other languages for training the system from scratch or fine-tuning the pretrained mBART models. We also require English, Tamil, and Inuktitut monolingual data for techniques such as back-translation, self-training, and creating language models for noisy-channel reranking. For low resource languages, Tamil and Inuktitut, we use all the available monolingual data, e.g. NewsCrawl + CommonCrawl + Wikipedia dumps for Tamil, and CommonCrawl for Inuktitut. For English, we only use NewsCrawl as the monolingual data because it is sufficiently large, high-quality, and in the news domain.

For the unconstrained track, we use Tamil monolingual data and Tamil-English mined bitext data from external sources based on CommonCrawl. The details are described in Section 2.2.

2.1 Data filtering

2.1.1 Bitext data

For each data source for each language pair, we remove duplicate sentence pairs and use `fastText` (Joulin et al., 2016a,b) language identification to remove sentence pairs where either the source or the target sentence is not predicted as the expected language. The resulting size of the bitext data of each language pair is shown in Appendix Table A.1.

2.1.2 Monolingual Data

We use monolingual data after `fastText` language identification filtering from all languages provided in WMT20 to train our mBART model. CommonCrawl contains a large quantity of data, but is also quite noisy as it is crawled from the web. Furthermore, the sentences are not in the news domain. To clean the data and select the sentences closer to the news domain, we apply the in-domain filtering method described in (Moore and Lewis, 2010) for languages that have NewsCrawl monolingual data. First, we train two n-gram language models (Heafield, 2011) on NewsCrawl and CommonCrawl respectively. Then, for each sentence from CommonCrawl, we obtain scores from these two language models, compute the difference between normalized log-probability, and we remove the lowest-scoring sentences. We heuristically examine the data and remove the bottom 30%-60% of sentences. Concretely, the scoring function is $H_{NC}(s) - H_{CC}(s)$, where s is the sentence, $H_{NC}(s)$ and $H_{CC}(s)$ are the word-normalized cross entropy scores for sentence s by n-gram language model trained on NewsCrawl and CommonCrawl data respectively.

We concatenate sentences from different sources and remove duplicate sentences for each language. We show the detailed dataset statistics in Appendix Table A.2.

2.2 Unconstrained setup for Tamil

In the unconstrained track, additional data can be used. We incorporate two additional sources of data: noisy bitext from data mining and monolingual data.

2.2.1 Mined bitext data

We use mined bitext data from CCMATRIX (Schwenk et al., 2019) and CCALIGNED (El-Kishky et al., 2019), two complementary mining strategies. Both approaches use the web data from unconstrained CommonCrawl to identify noisy bilingual matched pairs. CCMATRIX embeds monolingual sentences using `LASER` (Schwenk and Douze, 2017) multilingual sentence embeddings. To identify matching bitext pairs, the distance from each sentence to each other sentence is calculated based on the distance in the embedding space. For CCALIGNED, documents that could correspond to bitext pairs are aligned first at the document level, then at the paragraph level, and finally at the sentence level. In total, we include 2M aligned English-Tamil mined sentences.

2.2.2 Monolingual data

We used additional Tamil monolingual data from CommonCrawl snapshots between 2017-26 to 2020-10 extracted by CCNET (Wenzek et al., 2019). We break down the document-level structure from CCNET into sentences and apply further processing. We concatenate all the snapshots of the additional monolingual data, deduplicate the sentences, apply `fastText` language identification and remove sentences are not predicted as Tamil. The final data results in 125M sentences. Subsequently, we concatenate the unconstrained monolingual data with constrained monolingual data, and we use them for back-translation and training Tamil language model.

3 System overview

We use the Transformer (Vaswani et al., 2017) as our model architecture for all of our systems. To better train models with datasets in different sizes, we use random search to select the hyper-parameters that achieve the best BLEU score on the validation set. We use sentencepiece (Kudo and Richardson, 2018) to learn the subword units to tokenize the sentences. The details of selected hyper-parameters are listed in Appendix D. All our systems are trained with `fairseq`[1] (Ott et al., 2019).

3.1 Dataset tag

Training and decoding the model with an indication of domain (such as a specified dataset tag) (Kobus et al., 2016) is a technique that allows us to control the output domain of the trained system. Similarly, Caswell et al. (2019); Chen et al. (2019) show that adding specific tag to back-translated and self-translated data can improve model performance. We add dataset tags to all of our systems described in this paper, by pre-pending a domain specific tag to the source sentence during training. At test time, we sweep over all the possible tags that are used during training including "no tag", and we choose the tag that achieves the best BLEU score on validation set. We find that when training with dataset tag, the supervised systems are 0.9 and 0.5 BLEU score higher than the system trained without dataset tag for Ta → En and En → Ta respectively. See results in Table 1.

[1] https://github.com/pytorch/fairseq

3.2 Baseline systems

We investigate a variety of baseline approaches as the starting point for our models. For both Tamil and Inuktitut languages, we explore four different baseline systems, (1) bilingual supervised, (2) multilingual supervised, mBART pretraining with (3) bilingual and (4) multilingual fine-tuning. These systems are trained with constrained bitext and monolingual data. We will then improve these baseline models, as described in subsequent sections.

3.2.1 Bilingual supervised

To train the base bilingual systems, we pre-pend the dataset tag to the source sentence to differentiate data from different corpus and concatenate all data sources for that language.

3.2.2 Multilingual supervised

Arivazhagan et al. (2019) shows that multilingual model can improve the model performance of medium and low resource languages, as multilingual models are often trained on greater quantities of data compared to bitext models. Thus, we investigate if multilingual supervised models can be stronger starting points. We use all the bitext data between English and other languages provided in WMT20 to train many-to-one (XX → English) and one-to-many (English → XX) models. One challenge of multilingual training is different language directions have different quantities of data, and the high resource language can starve for capacity while low resource language can benefit from the transfer. To balance the trade-off between learning and transfer, we follow Arivazhagan et al. (2019) with a temperature-based strategy to sample sentences from different languages. Furthermore, for each direction, we optimize the transfer by selecting the best temperature and model checkpoint based on the BLEU score of the target language pair validation set.

3.2.3 mBART-pretraining with bilingual and multilingual fine-tuning

For mid and low resource languages, the quantity of available bitext may be low, but large resources of monolingual data exist. This monolingual data can be used in the form of pre-training, followed by subsequent fine-tuning into translation models. We use mBART (Liu et al., 2020) – a multilingual denoising pre-training approach – to pre-train our systems, which has shown substantial improvements com-

pared to training the model from scratch. First, we pre-train mBART across 13 languages (Cs, De, En, Fr, Hi, Iu, Ja, Km, Pl, Ps, Ru, Ta, Zh) on all monolingual data provided by WMT 20. For pretraining, we used a batch size of 2048 sequences per batch and trained the model for $240K$ steps. We learn the SPM jointly on all languages. We sample the same amount of sentences from monolingual data of all languages to learn a vocabulary of $130,000$ subwords. In the fine-tuning stage, we use exactly the same data sources as the bilingual supervised model and multilingual supervised model. For multilingual fine-tuning, previously people have built bitext translation systems by fine-tuning pretrained mBART models. Recent work Tang et al. (2020) extended this to multilingual fine-tuning, which can create multilingual translation models from multilingual pre-trained models. Different from Tang et al. (2020), we tune the temperature rate separately for the four language directions we focus on. In the multilingual fine-tuning stage, we use random search to sweep over dropout, learning rate, and temperature sampling factor, and we select the model checkpoint based on the BLEU score evaluated on the target language pair validation set.

3.3 Iterative back-translation (BT)

Back-translation (Sennrich et al., 2015) is an effective data augmentation technique to improve model performance with target side monolingual data. The method starts from training a target to source translation system, which is subsequently used to translate the monolingual data in the target language back to source language. Then the synthetic back-translated dataset is concatenated with the raw bitext data to train the source to target translation model. After the source to target model is improved, the same technique can be applied again to train the back-translation system in the reversed direction. We repeat the process for several iterations until no significant improvement is obtained.

In all of our back-translation systems, we follow Chen et al. (2019) to add dataset tags to both raw bitext data and back-translated data. We upsample the bitext data, and the upsampling ratio is selected based on parameter sweeping and validating the resulting improvement on the validation set. Beam search with beam size 5 is used when generating the synthetic sentences.

3.4 Noisy-channel reranking (NCD)

Reranking is a technique that uses a separate model to score and better select hypotheses from the n-best list generated by the the source to target model. To rerank our system output, we use the noisy-channel model (Yee et al., 2019) as the scoring model (Ng et al., 2019; Chen et al., 2019). Given a source and target sentence pair (x, y), the noisy-channel model scores it with

$$\log P(y|x) + \lambda_1 \log P(x|y) + \lambda_2 \log P(y) \quad (1)$$

where $\log P(y|x)$, $\log P(x|y)$ and $\log P(y)$ are the forward model, backward model and language model scores. The weights, λ_1 and λ_2, are tuned through random search on the validation set. All of our submitted test set hypotheses are ranked and selected by noisy-channel reranking.

The language models used in noisy-channel reranking are Transformers. For constrained track, we use the monolingual data as described in Section 2 to train the language models for English, Tamil. For Inuktitut, we find that the monolingual data is very limited and even smaller than the size of bitext data, therefore we concatenate the CommonCrawl data with the Inuktitut side of the bitext data together to train the Inuktitut language model. For unconstrained Tamil language model, we train on the constrained data with the additional unconstrained data extracted by CCNET as described in Section 2.2. The SPM size, model hyper-parameters, and evaluation of the language models can be found in Appendix B.

3.5 Self-training (ST)

Self-training (Ueffing, 2006; Zhang and Zong, 2016; He et al., 2019) is a method that leverage monolingual data in source language to improve the system performance. We use the trained source to target translation system to translate monolingual data in source language to target language. Similar to BT, the synthetic dataset can be concatenated with bitext data to train the source to target model again. We follow Chen et al. (2019) and use the noisy-channel model to select the top synthetic sentence when decoding from monolingual data into the source language. We inject the same types of noise to the source side of synthetic data as He et al. (2019).

Shen et al. (2019); Chen et al. (2019) both show that self-training can provide complementary improvement in addition to back-translation, espe-

Model	Ta → En	En → Ta	Iu → En	En → Iu
w/o tag	15.6	8.5	31.4	16.1
with tag	16.5	9.0	31.3	16.1

Table 1: Systems trained with and w/o dataset tags. The BLEU score is reported on validation set. We sweep all available dataset tags when decoding on validation set and report the best performing dataset tag. The BLEU scores of each dataset tag are reported in Appendix C

cially when (1) there is lack of target side monolingual data, (2) source side monolingual data is much similar to the domain of test set compared with target side monolingual data, and (3) the decoding method outperforms greedy decoding on the source to target model. Therefore, we experiment self-training on En → Iu due to greater quantities of in-domain source side monolingual data, on Iu → En in Nunavut Hansard domain with Inuktitut side of bitext data due to much more in-domain monolingual data on the source side, and on Ta → En because we observe great improvement from noisy-channel reranking. However, we only observe significant improvement on Ta → En system.

3.6 Fine-tuning (FT) on validation set

Fine-tuning is a technique to adapt the model to the target domain when the initial model is not trained with training data in the target domain. In both Tamil and Inuktitut, none of the training data is in news domain as the test data, therefore we fine-tune our final systems on a portion of the validation data and evaluate on the rest of hold-out validation data. For Tamil systems, we split the validation data with a 75-25 split, where 75% of the data is used for fine-tuning and 25% of the data is used for evaluation. Ta → En and En → Ta systems are fine-tuned and evaluated on the same split of validation dataset. For Inuktitut systems, we split the validation set based on the domain — Nunavut Hansard or news. For each domain, we split the validation data with a 75-25 split for fine-tuning and evaluation. We fine-tune our best performing Iu → En and En → Iu systems in domain on the corresponding validation set split.

4 Results

In this section, we describe the details of our systems, and we report SACREBLEU (Post, 2018) on the validation set for intermediate iterations and ablations. For our validation set fine-tuned systems, we report the BLEU score on our validation holdout set split. Our general strategy for all language directions was to identify the best performing baseline setting, then iteratively improve upon the baseline using back-translation and self-training. Finally, we apply noisy-channel reranking and fine-tuning on validation set to create our final submission.

4.1 Baseline

We explore four different baseline approaches as described in Section 3.2 for each language direction in the constrained setup, Inuktitut ↔ English and Tamil ↔ English. The detailed results are shown in Table 2.

First, bilingual models are trained with bilingual bitext data. Next, we focus on multilingual training. The multilingual supervised models are trained with all the available bitext data provided by WMT20. We use the same SPM as described in Section 3.2.3. For both bilingual and multilingual models, we initialize the model weights either randomly or with pre-trained mBART model weights. Therefore, for each language direction, we have four combinations, bilingual supervised, multilingual supervised, mBART + bilingual fine-tuning and mBART + multilingual fine-tuning. We use dataset tags for all systems, and we sweep the tag that performs the best when decoding on the validation set. Additional details and hyper-parameters are provided in the Appendix D.

For to-English directions, both multilingual models and mBART pretraining can get better model performance than bilingual supervised model as shown in Table 2. For Ta → En direction, mBART + multilingual fine-tuning performs the best with 20.4 BLEU, which outperforms bilingual supervised system by 3.2 BLEU score. For the Iu → En direction, mBART + bilingual fine-tuning works the best and gets 32.9 BLEU score, which outperforms bilingual supervised baseline by 2.8 BLEU score. However, for from-English directions, we do not observe similar advantages with either multilingual model or mBART pretraining, and a properly tuned bilingual supervised model achieves the best results for both directions. We get 8.0 BLEU score for En → Ta direction, and we get 16.1 BLEU score for En → Iu direction.

4.2 Tamil systems

4.2.1 Constrained Ta → En system

For the Ta → En system, we first use the En → Ta bilingual baseline system (ensemble) to gener-

System	Ta → En	En → Ta	Iu → En	En → Iu
bi.	17.2	8.0	29.7	16.1
multi.	18.2	7.1	30.7	15.8
bi-FT*	18.9	8.0	32.9	16.1
multi-FT*	20.4	7.4	32.5	16.0

Table 2: BLEU scores of baseline systems evaluated on the validation set. * Pre-trained on mBART.

ate back-translation data from English NewsCrawl data. We then train our first iteration back-translation system ("iter1-BT") with upsampled bitext (upsampling ratio tuned on the validation set). Similarly, we train our second iteration back-translation system ("iter2-BT") with upsampled bitext and back-translation data generated by En → Ta iter1-BT system (ensemble). The iter2-BT system (ensemble) is then used to generate ST data from Tamil NewsCrawl, CommonCrawl and Wiki data. We combine it with iter2-BT system's data to train the iter2-BT+ST system. Finally, we fine-tune this system on the validation set and apply noisy-channel reranking to select the hypotheses. We explore Transformer models of different capacities and choose Transformer *big* (with 8K feed-forward dimension) for a good balance of performance and training speed. For the iter2-BT+ST system (and its ensemble/finetuned version), we further enlarge the encoder to 10 layers given higher data abundance. We can see from Table 3 that our training pipeline improves model performance steadily (≥ 1.3 validation BLEU) after iterations, and in-domain fine-tuning as well as noisy-channel reranking are very helpful to alleviate the effects of train-test domain mismatch.

4.2.2 Constrained En → Ta system

For the En → Ta system, we first use the mBART+multi-FT baseline system for Ta → En to generate back-translation data from the monolingual data. We add different back-translation dataset tags based on the source of monolingual data and train our first iteration back-translation system ("iter1-BT") by tuning upsampling ratios on the bitext and back-translation datasets. For the model architecture, we explore the options of training Transformers from scratch and fine-tuning a pretrained mBART model and find that the former performs better with ensembles. Doing one iteration of training with back-translation data gives 5.8 BLEU increase (Table 3). We further train the second iteration back-translation system ("iter2-BT") with back-translation data generated from the best iter1-BT Ta → En system. As the gain from the second iteration is small (0.4 BLEU), we do not continue for the third iteration. Noisy-channel reranking is applied with the best systems from both language directions and the Tamil language model (Appendix B). We observe little gain (0.1 BLEU) and suspect it's due to the high perplexity of the language model. Further fine-tuning the iter2-BT model on the validation set gives 4.1 BLEU score improvement on the validation holdout set.

System	Ta → En	En → Ta
baseline	20.4	8.0
+ ensemble	21.2	9.0

back-translated data from unconstrained monolingual sources with back-translated data from WMT monolingual data from English and Tamil, with the WMT bitext and mined Ta → En data. We used the same BPE and vocabulary as the constrained system. The data was deduplicated, and the validation and test data removed if an exact match was present in the training data. The mined data was additionally cleaned to remove sentences longer than 250 BPE tokens, as well as bitext pairs where the length between the source and target was greater than 2.5x difference. Subsequently, we trained a large Transformer sequence-to-sequence model on the total combined data using various data domain tags. After training was complete, we further fine-tuned on the validation set, as described in Section 4.2.2. We applied noisy-channel reranking when decoding test data. The forward model is ensembled with two of the best performing fine-tuned models. The backward model is the best performing model in Section 4.2.1, which is ensembled with two fine-tuned models. The language model is unconstrained Tamil language model described in Section 3.4. We rerank from best 20 hypothesises generated by ensembled forward model, and we achieve 20.2 BLEU score on validation set.

4.3 Inuktitut systems

The Inuktitut validation and test set are composed of data from two different domains, the proceeding of the Legislative Assembly of Nunavut from Nunavut Hansard (NH) and news. We find that the model can be further improved if we optimize our translation training pipeline for these two domains separately, and therefore we train and report BLEU score separately for each domain. We also report the BLEU score on the whole validation set, where we use the domain-specific system to decode on the portion of the corresponding domain, concatenate the hypothesises and compute the BLEU score.

4.3.1 Constrained Iu → En systems

For the Iu → En system, we use En → Iu bilingual supervised system described in Section 4.1 for back-translation. The model used for decoding is an ensemble of 3 En → Iu models, and we decode from the English NewsCrawl data. We concatenate the back-translated data with bitext data and sweep the upsampling ratio of the bitext data to find the best ratio. We experiment with both mBART pretraining + bilingual fine-tuning and training from scratch, and we find that mBART + bilingual fine-tuning works better on Nunavut Hansard domain of validation set, and training from scratch works better on news domain. The hypothesis is that the English NewsCrawl monolingual data for back-translation is in-domain with the news domain validation set and there is huge amount of English NewsCrawl data, so the advantage of pretraining is not significant. We also experiment with self-training on Iu → En direction in Nunavut Hansard domain, where we use the source to target model (ensembled) to decode from the Inuktutit side of Nunavut Hansard 3.0 parallel corpus with noisy-channel reranking; however, we do not observe any improvement. The best result at the first iteration is from the back-translation system, which outperforms baseline system by 2.2 BLEU score (Table 4), where most of the gain comes from improvement on news domain.

We do not observe gains for doing the second iteration of back-translation for Iu → En system, and we suspect that it is due to lack of improvement for our En → Iu model from supervised approach to the first iteration. We then fine-tune the best iteration 1 Iu → En models on validation data for each domain. The final domain-specific systems are ensembled from the fine-tuned models and followed by noisy-channel reranking. To use noisy-channel reranking for Nunavut Hansard domain, we fine-tune the English language model described in 3.4 on English side of the Nunavut Hansard 3.0 training data provided in WMT20. The best Iu → En system we submit has 40.2 BLEU score on our validation holdout set.

4.3.2 Constrained En → Iu systems

We experiment with both self-training and back-translation with the best baseline systems reported in 4.1 to improve En → Iu system. For self-training,

we use ensembled supervised En → Iu model and beam decoding with beam size 5 to decode from English monolingual data. We decode from the English side of Nunavut Hansard 3.0 parallel corpus to train the model for Nunavut Hansard domain, and we decode from the English NewsCrawl data for news domain. However, we do not observe improvement for news domain, and there is only mild improvement (0.3 BLEU) for Nunavut Hansard domain as shown in Table 5. For back-translation, we use iteration 1 Iu → En news domain model from 4.3.1 to decode constrained Inuktitut CommonCrawl data. We get no improvement on Nunavut Hansard domain and mild improvement (0.2 BLEU) on news domain. We use self-training system for Nunavut Hansard domain and back-translation system for news domain, and it achieves 16.3 BLEU score on the validation set, which is merely 0.2 BLEU score improvement over baseline system. We then fine-tune the best systems we get on domain-specific validation set splits, followed by ensembling and noisy-channel reranking. The fine-tuning is very effective for the news domain, where we get 9.1 BLEU score improvement. This is expected because we do not have any training data from news domain. Our final submitted system achieves 22.0 on our validation holdout set.

Submitted system	BLEU
Ta → En	21.5
En → Ta	12.6
En → Ta (unconst.)	13.7
Iu → En	27.9
En → Iu	13.0

Table 6: Results of our best submitted systems of each direction. We report BLEU scores on newstest2020.

5 Conclusion

This paper describes Facebook AI's Transformer based translation systems for the WMT20 news translation shared task. We focused on two low-resource languages pairs, Tamil ↔ English and Inuktitut ↔ English, and we explored the same set of techniques, including dataset tagging, mBART pretraining and fine-tuning, back-translation and self-training, fine-tuning on domain-specific data, ensembling, and noisy-channel reranking. We demonstrated strong improvements by stacking these techniques properly on three language directions, Ta → En , En → Ta , and Iu → En . The En → Iu direction is difficult to improve due to lack of target side monolingual data. Surprisingly, self-training does not work on En → Iu either even we have huge amounts of in-domain English side monolingual data. We are interested in continued exploration on how to better leverage source side monolingual data to improve En → Iu and other low resource languages where we do not have enough target side monolingual data.

6 Acknowledgements

We thank Marc'Aurelio Ranzato for providing discussion and guidance during the competition, Vishrav Chaudhary for sharing insightful data cleaning approaches, Guillaume Wenzek for previous work on ccNET for monolingual data used in unconstrained setting, Yuqing Tang for the work of mBART pretraining and multilingual fine tuning, Ahmed El-Kishky and Holger Schwenk for sharing their mined data for Tamil, Sergey Edunov for sharing cleaned up dataset to speed up our early exploration, and Michael Auli for sharing experience about noisy-channel reranking technique.

A Constrained data

In this section, we list the statistics for all the constrained datasets we use to build for our systems.

Bitext data Table A.1 shows the bitext data we used for multilingual systems. We use all bitext data between English and other 11 languages provided in WMT 20 except a couple of sources. We do not include the data back-translated by other system to avoid introducing bias. We do not include CzEng 2.0 for Czech nor CCMT for Chinese due to human mistake. We follow the filtering steps described in Section 2.1.1, and the size of dataset for each language pairs are listed in Table A.1.

Monolingual data Table A.2 shows the list of monolingal data we use for mBART-pretraining with 13 languages. We follow Section 2.1.2 to filter the monolingual data, and we list the amount of data before and after the filtering step.

B Language model used in noisy-channel reranking

Language model is required in the noisy-channel reranking system. We learn the BPE subwords with sentencepiece, and we train the Transformer based causal language models with `fairseq` in fp16 mode. The model size and hyper-parameters are tuned based on the perplexity of newsdev2020 validation sets per language. We describe the data and hyper-parameters of each language below, and we report the perplexities in Table B.1.

English language model We train our English language model with the high quality NewsCrawl data provided by WMT 20. We use the same filtering steps in Section 2.1.2 for NewsCrawl. We learn the BPE with 32K vocabulary size. We train the transformer-based model with 36 transformer layers, 1280 embedding dimension size, 5120 ffn dimension size, 20 attention heads and resulting in 749M parameters. The optimizer is Adam (Kingma and Ba, 2015) optimizer with $beta1 = 0.9$ and $beta2 = 0.98$. We use polynomial decay learning rate scheduler with 0.005 learning rate and 0.1 dropout rate. The maximum tokens are 4096 for each batch per GPU, and we train with 64 GPUs for 58K updates. As we show in Table B.1, this model achieves 23.3 perplexity on English side of Ta-En newsdev2020 set, 25.3 perplexity on news portion of Iu-En newsdev2020 set, and 29.7 perplexity on Nunavut Hansard portion of Iu-En newsdev2020 set. The perplexity on news validation sets are lower than none-news validation set. We use the English language model to rerank Ta $\rightarrow$ En system and news domain of Iu $\rightarrow$ En system.

To better rerank Iu $\rightarrow$ En hypothesises for Nunavut Hansard domain, we fine-tune the English language model on English side of Nunavut Hansard 3.0 parallel corpus. The perplexity on Nunavut Hansard portion of Iu-En newsdev2020 set is significantly improved from 29.7 to 8.1. We use the fine-tuned English language model to rerank the Nunavut Hansard domain of Iu $\rightarrow$ En system.

Tamil language model We train the Tamil language model for constrained En $\rightarrow$ Ta system with all the available Tamil monolingual data preprocessed in Section 2.1.2. The BPE vocabulary size is 32K. We train the transformer-based language model with 24 transformer layers, 1024 embedding size, 4096 ffn embedding size, 16 attention heads and resulting in 335M parameters. We use Adam optimizer with $beta1 = 0.9$ and $beta2 = 0.98$. We use polynomial decay learning rate scheduler with 0.005 learning rate and 0.1 dropout rate. The maximum tokens are 8192 for each batch per GPU, and we train with 16 GPUs for 46K updates. The model achieves 61.8 perplexity on Tamil side of Ta-En newsdev2020 set.

For unconstrained En $\rightarrow$ Ta system, we use both constrained Tamil monolingual data and the additional Tamil monolingual data described in Section 2.2. We share the same 32K BPE vocabulary as constrained Tamil language model. We use a larger transformer model with 32 transformer layers, 1024 embedding size, 4096 ffn embedding size, 8 attention heads. We use Adam optimizer with $beta1 = 0.9$ and $beta2 = 0.98$. We use cosine learning rate scheduler with 0.0001 learning rate and 0.3 dropout rate. The maximum tokens are 3072 for each batch per GPU, and we train with 32 GPUs for 69K updates. The model achieves 40.6 perplexity on Tamil side of Ta-En newsdev2020 set, which is better than the constrained Tamil language model.

Inuktitut langauge model The Inuktitut language model is trained with Inuktitut side of Nunavut Hansard 3.0 parallel corpus and the constrained Inuktitut monolingual data provided by WMT 20. The BPE vocabulary size is 5K. We train the transformer-based language model with

6 transformer layers, 512 embedding size, 4096 ffn embedding size, 8 attention heads and resulting in 34M parameters. We use Adam optimizer with $beta1 = 0.9$ and $beta2 = 0.98$. We use inverse square root learning rate scheduler with 0.0005 learning rate and 0.3 dropout rate. The maximum tokens 2048 for each batch per GPU, and we train with 8 GPUs for 89K updates. The model achieves 34.9 perplexity on Nunavut Hansard domain of Iu-En newsdev2020 set, and 81.69 perplexity on news portion of Iu-En newsdev2020 set.

C The effect of dataset tag at decoding time

We train our systems with dataset tag, and we sweep the dataset tags by add different tags to the same validation set and select the best performing tag. Table C.1 and C.2 show the system performance across different dataset tags.

First, we observe that sweeping the best performing dataset tag at decoding time is necessary. Using "no tag" to decode works the best for both Ta → En and En → Ta systems; however, using specific dataset tags works better for Iu → En and En → Iu systems. Second, the large BLEU score variations when decoding with different dataset tags show that the tags help the model to better adapt to different domains.

Overall, systems trained with dataset tags works better than trained without dataset tag as we show in Table 1.

D Hyper-Parameters

In this section, we report the hyper-parameters we use. For all of our translation systems, we use transformer based encoder-decoder model with shared embedding across encoder, decoder input and output embedding. We use Adam optimizer with $beta1 = 0.9$ and $beta2 = 0.98$, inversed square root learning rate scheduler, and 4000 warm-up steps with linearly increased rate. The loss is cross-entropy with label smoothing (Szegedy et al., 2016). We use the same batch sizes with maximum number of tokens 4096, and all models are trained with fp16. We sweep other hyper-parameters with random search, and we select the best performing system based on the evaluated BLEU scores on validation sets.

mBART pretraining We train the denoising mBART model with the constrained monolingual data from 13 languages described Section 2.1.2. We learn joint BPE across all languages with vocabulary size 130K. The transformer based encoder-decoder model has 12 encoder and decoder layers, 1024 embedding dimension, 4096 ffn embedding dimension and 16 attention heads, resulting in 487M parameters. We train the model with 0.0003 learning rate, 0.1 dropout rate, and no label-smoothing. We train the model with 256 GPUs for 240K updates.

Tamil systems For Ta → En, the best performing systems are mBART+multilingual fine-tuning model for baseline system, back-translation system for iteration 1 and BT+ST system for iteration 2. We report the hyper-parameters of the best performing system at each iteration in Table D.1.

For En → Ta, the best performing systems are bilingual supervised model for baseline system, back-translation system for iteration 1 and iteration 2. We report the hyper-parameters of the best performing system at each iteration, including the unconstrained system in Table D.2.

Inuktitut systems For Iu → En, the best baseline system is the mBART pretraining with bilingual fine-tuning. In iteration 1, we tune the model separately for Nunavut Hansard domain and news domain. The best Nunavut Hansard domain model is mBART pretraining with bilingual fine-tuning on bitext and news back-translated data, and the best news domain model is the back-translation model train from scratch. For En → Iu, the best baseline system is bilingual supervised model. Similar to Iu → En system, we tune the model separately for Nunavut Hansard domain and news domain in iteration 1. The best system for Nunavut Hansard domain is self-training model train from scratch, and the best system for news domain is the back-translation model train from scratch. We report the hyper-parameters of the best performing Iu → En and En → Iu systems at each iteration in Table D.3 and D.4.

Linguistically Motivated Subwords for English-Tamil Translation: University of Groningen's Submission to WMT-2020

Prajit Dhar **Arianna Bisazza** **Gertjan van Noord**

University of Groningen

{p.dhar, a.bisazza, g.j.m.van.noord}@rug.nl

Abstract

This paper describes our submission for the English-Tamil news translation task of WMT-2020. The various techniques and Neural Machine Translation (NMT) models used by our team are presented and discussed, including back-translation, fine-tuning and word dropout. Additionally, our experiments show that using a linguistically motivated subword segmentation technique (Ataman et al., 2017) does not consistently outperform the more widely used, non-linguistically motivated SentencePiece algorithm (Kudo and Richardson, 2018), despite the agglutinative nature of Tamil morphology.

1 Introduction

In this paper we present the neural machine translation (NMT) systems submitted to the WMT-2020 English-Tamil (EN→TA) news translation task. This task is challenging mainly for two reasons:

1. Differing syntax: English is an Indo-European language which is fusional and SVO (Subject-Verb-Object). On the other hard, Tamil is part of the Dravidian language family and is a SOV language that is agglutinative. A good NMT system is expected to discern the various morphological forms on the Tamil target side.

2. Scarcity of training data: Prior to WMT-2020, there existed only a few corpora for parallel EN-TA sentences (Ramasamy et al., 2012; Germann, 2001). This left us with the choice of either only utilizing the low amount of parallel sentences or finding out ways of artificially enlarging the training data.

Through our submission we wish to provide solutions to the following questions:

- Is linguistically motivated subword segmentation beneficial for EN-TA translation?
- Can the addition of TA monolingual data compensate for the small amount of parallel EN-TA sentences despite the domain mismatch?
- Can fine-tuning on a corpus of Indian news improve quality on the WMT news translation task?

We start our paper with a short description of the Tamil language before delving into the various techniques adopted by our submitted NMT systems.

2 Tamil Language

Tamil is a Dravidian language spoken by around 80 million people. Tamil morphology is agglutinative and suffixal, i.e words are formed by suffixing morphemes to a lemma (Annamalai et. al 2014, cited in Sarveswaran et al. (2019)). Tamil suffixes can be either derivational (marking a change in PoS and/or meaning) or inflectional. In particular, nouns in Tamil are inflected for number, gender, case and animacy while verbs are inflected for tense, mood, aspect, negation, interrogation, information about emphasis, speaker perspective, sentience or rationality, and conditional and causal relations. Table 4 shows examples of the case forms in singular for the noun புத்தகம ’book’.

All the aforementioned statements substantiate the fact that Tamil morphology is highly complex. In fact, Ramasamy et al. (2012) identified 716 inflectional rules for nouns and 519 rules for verbs. Furthermore, designing a translation system for Tamil is challenging given the lack of training data (compare the sizes of Japanese and Tamil parallel datasets in WMT 2020, both agglutinative, however having vastly different training data; 25M sentences and 630k, respectively).

Proceedings of the 5th Conference on Machine Translation (WMT), pages 126–133
Online, November 19–20, 2020.

3 Previous Work

One of the earliest automatic translation systems for English→Tamil was by Germann (2001). They created a hybrid statistical/rule-based machine translation (SMT) system and trained it on only 5k EN-TA parallel sentences. Ramasamy et al. (2012) created SMT systems (phrase-based and hierarchical) that were trained on a much larger dataset of 190k parallel sentences. They also performed pre-processing steps involving morphological rules based on Tamil suffixes that improved upon the BLEU score of the baseline model (from 9.42 to 9.77). Their dataset (henceforth called UFAL) became the default benchmark for EN-TA translation systems until 2019, and we also use it in our experiments as an additional (general-domain) development set.

To the best of our knowledge, there have only been a handful of NMT systems trained on EN→TA. For the Indic languages multilingual tasks of WAT-2018, Sen et al. (2018), Dabre et al. (2018) and Ojha et al. (2018) reported BLEU scores for EN→TA. The Phrasal-based SMT system of Ojha et al. (2018) with a score of 30.53 BLEU outperformed the NMT systems of Sen et al. (2018) (11.88) and Dabre et al. (2018) (18.60), suggesting that the NMT systems were not suitable for translating a highly morphological language such as Tamil. However, the following year, Philip et al. (2019) outperformed Ramasamy et al. (2012) on the UFAL dataset with a BLEU score of 13.05. They report that techniques such as domain adaptation and back-translation can make training NMT systems on low-resource languages possible.

4 Datasets

For our constrained systems, we restrict ourselves to the datasets provided by WMT.

Parallel Table 1 presents the various parallel corpora along with their size and genre. The various corpora come from various sources and differ considerably in size. We also observe a very large difference in number of tokens between the two languages, with around 5 times more English tokens than Tamil tokens.

Monolingual Table 2 presents the monolingual Tamil corpora used in our experiments. Monolingual data is about 3 times larger than the parallel data in terms of tokens.

4.1 Pre-processing

For both parallel and monolingual data, the following steps are carried out sequentially:

- Sentences are tokenized and segmented by one of the segmentation algorithms described in the following section.
- Sentences longer than 150 tokens are removed.
- Sentences whose target to source ratio is below 0.7 are retained. This ratio is calculated based on the sentence lengths.
- Similar to Philip et al. (2019), a language match threshold is applied. Sentences rated 98% or higher are retained.
- Duplicate sentences are removed.

5 Methods

5.1 Segmentation

We compare two segmentation techniques: data-driven subwords and linguistically motivated subwords.

Subword segmentation refers to fully data-driven, non linguistically motivated segmentation algorithms (Sennrich et al., 2016c; Kudo and Richardson, 2018) that generate sub-words based on simpler frequency criteria to attain a predetermined vocabulary size. In our experiments we try out different vocabulary sizes as well as generating the subwords either individually for each language or jointly learning on both. The SentencePiece (**SP**) implementation (Kudo and Richardson, 2018) is used to perform this segmentation.

Linguistically Motivated Vocabulary Reduction (LMVR) is an unsupervised morphological segmentation algorithm based on Morfessor FlatCat (Kohonen et al., 2010; Grönroos et al., 2014) and proposed by Ataman et al. (2017). LMVR works by imposing an extra condition on the cost function of Morfessor so as to favour vocabularies of the desired size. When comparing regular Subword tokenization to LMVR, Ataman et al. (2017) report a +2.3 BLEU improvement on the English-Turkish translation task. Similar to SP, we need to set the vocabulary size prior to running the segmentation. LMVR models are trained separately for Tamil and English, which are then used to segment the respective datasets.

5.2 Back-translation

In order to artificially increase the training data, we employ back-translation (BT) (Sennrich et al., 2016b). We consider two variations of this approach:

TaggedBT was presented by Caswell et al. (2019) and is similar to the original BT technique of Sennrich et al. (2016b), with the major difference being the addition of a special tag (here <BT>) in front of every back-translated English sentence. Caswell et al. (2019) had shown that this simple manoeuvre resulted in a higher BLEU score when compared to untagged BT based NMTs.

StupidBT Rather than performing actual BT which is expensive, Burlot and Yvon (2018) carry out the following:

1. Copy the target side data to the source side.

2. Prepend each token on the source side with a special id. For example, the token *tablet* becomes *bt_tablet*.

This simple and cost-effective technique was shown to perform almost on a par with regular BT on the English→French translation task.

5.3 Fine-tuning

Fine-tuning or transfer learning (Pan and Yang, 2010) is an effective technique to address a domain mismatch between the training set and the testset. While the testset consists of excerpts from newspapers, the training set consists of corpora with genres ranging from religious, political to movie subtitles. In fact, only a third of UFAL is news-oriented. A strategy to circumvent the domain mismatch is to fine-tune a pre-trained NMT system on a more domain specific dataset. Unfortunately the UFAL corpus is not domain tagged, so the news-only sentences cannot be easily retrieved.

We also excluded the PIB dataset due to its small size and large amount of almost identical sentences.

We hence perform fine tuning on the PMI dataset: This dataset consists of the sentences that were crawled from the Prime Minister of India's blog, with matters that are mostly political in nature. Despite the different content, we expect this corpus to be the closest in genre to the testset among the remaining parallel corpora.

5.4 Word Dropout

First introduced in Gal and Ghahramani (2016), the word dropout technique was modified by Sennrich et al. (2016a) to randomly drop tokens in-

stead of types during training. They reported an increase of 4-5 BLEU for the English↔Romanian language pair. Furthermore, Sennrich and Zhang (2019) report that introducing word dropout into NMT systems in low-resource settings leads to improvements in BLEU scores. We would hence like to investigate if the same improvements can be observed for EN-TA.

6 Experimental Setup

All our NMTs are developed using Fairseq (Ott et al., 2019). Following the architecture setup of Philip et al. (2019) the Transformer-Base implementation (BASE) is used, with slight changes to a few parameters, which are explained below. The encoder and decoder are both set to 5 layers with embedding dimension of 512 and 8 attention heads. The hidden layer dimension is 2048 and layer normalization is applied before each encoder and decoder layer. Other parameters were set as follows: dropout (0.001), weight decay (0.2) and batch size of 4k tokens. Our loss function is cross-entropy with label smoothing of 0.2. The model is trained for 100 epochs with early stopping criterion set to 3.

Segmentation The various segmentation algorithms are trained on the training data prior to the translation task. We report results with the following vocabulary sizes: 5k (source-target joint), 5k/5k, 10k/10k, 15k/15k and 20k/20k (source/target disjoint).

Back-Translation In order to perform BT, we first need to train a NMT model in the reverse direction, i.e. TA→EN. A Transformer based architecture is also used here. Our best configuration was: embedding and decoder having 6 layers, embedding layer having 512 dimensions and 6 attention heads with the rest of the parameters set as BASE. This model achieves a BLEU score of 18.27 on the UFAL TA-EN testset.

Fine-Tuning For the fine-tuning step, we take the pretrained BASE models and continue training them on the PMI dataset. An exhaustive search is done to find the best configurations for the fine tuning. The parameters with which we experimented are the learning rate, batch size, dropout and the value of label smoothing. Eventually we selected the following fine-tuning setup: learning rate of 0.002, batch size of 128, dropout of 0.3, label smoothing with factor of 0.3, and early stopping after 5 epochs without improvements.

Word Dropout Following Sennrich and Zhang (2019) we set the source word dropout to 0.3, i.e. the probability of a source word, in a batch, being dropped prior to training is 0.3.

7 Results

We report BLEU scores on three testsets: the UFAL testset (Ramasamy et al., 2012), half of the WMT2020 devset (DEV)[1] and the official WMT2020 testset. Given the rich morphology of Tamil, we also report CHRF scores (Popović, 2015) on the WMT2020 testset. We ran the program chrF++.py[2] with the arguments -nw 0 -b 3 to obtain the CHRF score.

From prior experimentation we found that a jointly trained SP model resulted in better BLEU when compared to separate training for each language, and hence perform the majority of SP experiments in Table 3 using a joint segmentation. On the other hand, LMVR being linguistically motivated is supposed to be trained independently for each language.

The last two contrastive experiments (Exp8.2 and Exp11.2) were run after the evaluation phase to better assess the impact of LMVR on translation quality in our best systems.

The following observations can be made based on the results:

Differences across testsets The trends are often inconsistent across testsets. Exp2 gave the highest BLEU score on UFAL (11.8) but a low BLEU score for DEV and WMT. On the other side, Exp11 (and Exp11.2) provided us the highest BLEU score on the official WMT testset, but a low 10.5 for UFAL. These variations could be attributed to the nature of the testsets and our training regime. Because we focused on improving our NMT systems to adapt to the news genre of WMT testset, this resulted in loss of translation accuracy of the UFAL testset, which was a mixture of three domains (one of them being news).

Effect of Back-translation Across both segmentation techniques, back-translation proved to be beneficial. Despite previously reported results, we found that fully fledged back-translation

[1] We randomly select one half of the WMT2020 devset for validation and use the remaining half for evaluation (DEV).

Exp11	BASE +TaggedBT+FT	LMVR	15k/15k	10.2	9.7	6.0	46.1
Exp13	BASE +TaggedBT+WD+FT	LMVR	15k/15k	10.7	**10.2**	**6.5**	**50.9**
Exp8.2	BASE +TaggedBT	SP	15k/15k	11.3	9.1	6.3	44.2
Exp11.2	BASE +TaggedBT+FT	SP	15k/15k	10.5	9.7	6.6	47.2

Table 3: English-Tamil results on three datasets: the general-domain UFAL (Ramasamy et al., 2012), our news development set (DEV) and the official WMT2020 news testset (WMT). Exp11 (in bold) was our official submission to WMT2020. SP refers to SentencePiece and LMVR to (Ataman et al., 2017). Dictionary size is given as one number for source-target joint segmentation, or as two numbers for source/target size when disjoint. FT and WD stand for fine-tuning and word dropout, respectively.

(TaggedBT) works considerably better than its cheaper approximation (StupidBT) on DEV, but not on the UFAL testset. While DEV reported increases of +0.3 (Exp2 vs. Exp3), a drop of -0.1 in BLEU was seen for UFAL. This could be due to the fact that Newscrawl was a major constituent of the monolingual corpora, that were used to train the TaggedBT systems. Also, when comparing a BASE system to one with TaggedBT (Exp1 vs. Exp3), we find an increase of +0.3 in BLEU. Given the DEV result, we decided to use fully fledged TaggedBT for the rest of our experiments.

SP vs. LMVR Based on our initial experiments, LMVR seemed to outperform SP. For instance, when comparing the TaggedBT systems with SP and LMVR (Exp3 vs. Exp9) we see a +0.5 increase in BLEU.

However, after the official submission, we performed additional contrastive experiments to account for LMVR having a much larger and disjoint vocabulary size (see Exp 8.2 vs. Exp8 and Exp11.2 vs. Exp11). In both settings, the linguistically motivated segmentation was actually outperformed by SentencePiece (+0.3 higher BLEU score on WMT). On the other hand, results were inconclusive when looking at the CHRF scores: namely, LMVR is much better than SP in the non fine-tuned system (Exp8 vs. Exp8.2), but slightly worse in the fine-tuned system (Exp11 vs. Exp11.2). These results seem to reveal a complex interplay between the effect of domain adaptation and the choice of an optimal segmentation strategy.

Effect of vocabulary size For our BT model with LMVR segmentation, we report the scores for four different vocabulary sizes (Exp6 to Exp9): among these, 15k for each language (Exp8) gives the best BLEU score of 9.3 on DEV. Therefore we use this size for the remaining experiments.

Effect of fine tuning When we compare models to their counterparts that were additionally fine-tuned, we observe a slight increase in the DEV BLEU score for the LMVR systems (compare Exp8 vs. Exp11) but unfortunately no effect on the WMT testset. This is probably due to the fact that the dataset on which we fine-tuned (PMI) was not close enough to the domain of the news translation testset.

Effect of word-dropout Word dropout was introduced to our best system, that is the one using TaggedBT and a LMVR vocabulary size of 15k/15k. The resulting system (Exp13) turned out to be our best performing system overall, but was not ready in time for the official submission. We find that the addition of word dropout resulted in a BLEU increase of +0.5 on DEV and WMT, and a large CHRF increase (+4.8) on WMT, which confirms the usefulness of this technique on a new lan-

Case	Case Marker	Tamil	SP	LMVR
Nominative	−∅	புத்தம் puththagam 'book'	புத்த+கம் puththa+gam	புத்த+கம் puththa+gam
Accusative	−அ −a	புத்தகம puththagama 'the book'	புத்தக+ம puththaga+ma	புத்த+க+ம puththa+ga+ma
Dative	−உக்கு −ukku	புத்தகமுக்கு puththagamukku 'to/for the book'	புத்தக+மு+க்கு puththaga+mu+kku	புத்த+கம+உக்கு puththa+gam+ukku
Genitive	−ஓட −ooda	புத்தகமோட puththagamooda 'the book's'	புத்தக+மோட puththaga+mooda	புத்த+க+மோ++ட puththa+ga+moo+da
Instrumental	−ஆல −aala	புத்தகமால puththagamaala 'by the book'	புத்தக+ம்+ஆல puththaga+m+aala	புத்த+க+மா++ல puththa+ga+maa+la
Sociative	−ஓட −ooda	புத்தகமோட puththagamooda 'along with the book'	புத்தக+மோட puththaga+mooda	புத்த+க+மோ++ட puththa+ga+moo+da
Locative	−ல −la	புத்தகம்ல puththagamla 'in the book'	புத்த+கம்+ல puththa+gam+la	புத்த+கம்+ல puththa+gam+la
Ablative	−லருந்து −larundhu	புத்தகம்லருந்து puththagamaala 'from the book'	புத்த+கம்+ல+ருந்து puththa+gam+la+rundhu	புத்த+கம்+ல+ருந்து puththa+gam+la+rundhu

Table 4: Different inflections of the Tamil singular noun புத்தகம். Columns SP and LMVR show the segmentations resulted by the SentencePiece (SP) and LMVR algorithms respectively.

guage pair.

8 Analysis

We also performed two small qualitative studies on the best systems based on segmentation. First, we compare how the segmentation algorithms segment the Tamil word புத்தகம் 'book'.

Secondly, using the example of the word *book* we observe how the systems translate the word to and from Tamil (Table 5).

Segmentation Table 4 shows how the word புத்தகம் and its various case forms are segmented by the segmentation techniques. The main differences that we observe are:

- LMVR and SP generated the same segmentation for three cases: nominative, locative and ablative.
- LMVR always generated segmentations with the base sub-word புத்த/puththa for all the case forms while SP generated the segments புத்த/puththa or புத்த/puththaga. This confirms the observations of Ataman et al. (2017), that LMVR produces more morphological segments.
- LMVR, on average, resulted in more segments per token than SP.

Translation Quality For the compound *comic-book*, the SP system translates it as நகைச்சுவை புக்/nakaiccuvai puk, i.e. *comedy book*, with the word புக்/puk being a direct transliteration for *book* and hence incorrect. On the other hand, LMVR provides the correct translation.

There were in total two occurrences of the nominative form of the புத்தகம்/puththagam, which were correctly translated by the two systems. The same was observed for the locative form புத்தகம்ல/puththagamla.

An example where both systems fail to translate the phrase *by the book* as in the sentence "I have every reason to believe they have done everything by the book and ...". The SP system provides

English	Tamil	SP	LMVR
comic-book	காமிக் புத்தக kaamik puththga	நகைச்சுவை புக் nakaiccuvai puk	காமிக் புத்தக kaamik puththga
book	புத்தகம் puththagam	புத்தகம் puththagam	புத்தகம் puththagam
in the book	புத்தகம்ல puththagamla	புத்தகம்ல puththagamla	புத்தகம்ல puththagamla
notebook	புத்தகத்தைத் puththagaththait	புத்தகட்டி puththagatti	குறிப்பேடு kurippetu
by the book	சட்டத்தைப் cattattaip	புத்தகமால் puththagamaal	விதிப்படி vithippati

Table 5: Qualitative Analysis of the Tamil word புத்தகம்/*puththagam* along with selected translations of the English word *book*

a grammatically correct form for book (ablative), it is however semantically incorrect. Meanwhile, the LMVR system generates the word விதிப்படி/vithippati meaning 'by rule' while the reference word has the meaning சட்டத்தைப்(bill).

Finally we observed with the word *notebook* that SP generated a non-existent word and LMVR provided an another translation for the English word *notebook*.

In the future, we aim to conduct in-depth analysis on what and which morphological features are captured by the NMT systems.

9 Conclusion

Although our results were not competitive with the other submissions for the EN-TA task, our paper presents the various settings that leads to an improvement in EN-TA translation. Mainly, we found that linguistically motivated subword segmentation (Ataman et al., 2017), which was previously shown to benefit translation from/into various non-Indian languages, does not consistently outperform the widely used SentencePiece segmentation despite the agglutinative nature of Tamil morphology. We also found that, for our English-Tamil systems, fully-fledged back-translation remains more competitive than its cheaper alternative (Burlot and Yvon, 2018). And finally, we observe a noticeable CHRF gain when adding word dropout (Sennrich et al., 2016a) to our best model.

The TALP-UPC System Description for WMT20 News Translation Task: Multilingual Adaptation for Low Resource MT

Carlos Escolano, Marta R. Costa-jussà, José A. R. Fonollosa,

Universitat Politècnica de Catalunya, Barcelona

Abstract

In this article, we describe the TALP-UPC participation in the WMT20 news translation shared task for Tamil-English. Given the low amount of parallel training data, we resort to adapt the task to a multilingual system to benefit from the positive transfer from high resource languages. We use iterative back-translation to fine-tune the system and benefit from the monolingual data available. In order to measure the effectivity of such methods, we compare our results to a bilingual baseline system.

1 Introduction

Modern NMT systems such as Transformer require large amounts of training data in order to obtain good generation results. For this reason, low resource languages represent a good opportunity to explore new techniques to treat data more efficiently and benefit from available sources of data like monolingual corpora.

From the WMT20 news tasks proposed languages we are presenting our results on the English-Tamil language pair, Tamil is an official language from India, Sri Lanka, and Singapore having approximately 75 million native speakers. It belongs to the Dravidian family, originated in Asia.

Two principal reasons can make Tamil a challenging language for machine translation: script and agglutination. Tamil's script consists of 12 vowels and 18 consonants plus one special character, allowing the combination of 247 possible characters. Compared to the Latin script employed by most western languages, it is an order of magnitude higher in the number of possible characters.

Also, by agglutination, suffixes can be added to root words to form new ones. These words can lead to multiple words in the target language in the context of machine translation, which may affect attention and decoding in NMT systems.

This work discusses the system proposed for the evaluation in which we combine the use of multilingual parallel data with monolingual data to boost the performance of our proposed NMT system.

2 Low Resource NMT

Modern NMT systems benefit from having hundreds of thousands or even millions of parallel sentences. When working with low resource language pairs, the two main approaches are the use of monolingual corpora and multilingual NMT. While parallel data may be difficult to obtain for low resource languages, monolingual data is usually more available, as it does not require any additional labeling.

A common approach to benefit from monolingual data is back-translation (Sennrich et al., 2016a), which consists of translating a monolingual corpus to generate synthetic corpora that can be later employed to continue training. Similar techniques create a synthetic pseudo-parallel corpus through a pivot language (Casas et al., 2019) that can be then trained similarly to back-translation when data is available between the desired language pair and a pivot high resource language. More recently, iterative back-translation (Hoang et al., 2018) was proposed. This technique allows the system to generate synthetic data while updating the system, so better the new data improves as the system trains. On the other hand, several works on Multilingual NMT have shown benefits for low resource language pairs by allowing positive transfer from the high resource languages, boosting the performance of the low resource ones. Different architectures have been proposed that show this behavior, from universal models where all parameters are shared between all languages (Johnson et al., 2017), to architectures that share a common device that maps representations into a shared represen-

Proceedings of the 5th Conference on Machine Translation (WMT), pages 134–138
Online, November 19–20, 2020.

tation space (Firat et al., 2016; Zhu et al., 2020), to architectures that do not share parameters (Escolano et al., 2019; Escolano et al.; Schwenk and Douze, 2017).

In the context of the WMT20 Tamil-English news shared task, as the provided parallel data is limited, we resorted to a combination of both proposed methods by incrementally train the new language pair into a Multilingual NMT system using the provided parallel data, to later fine-tune the system using iterative-back-translation with monolingual corpora.

3 Related Work

Previous works (Choudhary et al., 2018) have shown that Indian languages are usually a challenge for NMT systems due to their difference in terms of vocabulary and grammar compared to western languages such as English. Also, standard preprocessing methods do not always work well with them, so specific solutions are required to obtain good results.

In the context of NMT, previous systems, such as MIDAS (Choudhary et al., 2018), proved that the use of subword units leads to significant improvements in translation quality when applied to Tamil by preventing Out of Vocabulary words in at generation time.

4 Corpora and Data Preparation

All proposed systems in this work are constrained using exclusively data provided by the task's organization. The multilingual initial system was trained using *Europarl v8*, for all translation directions between English, French, Spanish, and German. For English-Tamil *PMIndia*, *Tanzil v1*, *The UFAL EnTam corpus*, The *NLPC UOM En-Ta corpus*, *Wikimatrix*, and *Wikitiles*. As monolingual Tamil data, we used News Crawl, while for English, we used *News-commentary*.

We processed all non-Tamil data following *Moses* (Koehn et al., 2007) scripts provided by the organization. For each one, we applied punctuation normalization, tokenization, and true-casing. Then each language is independently tokenized using BPE (Sennrich et al., 2016b) with 32 thousand operations. Table 1 the estatistics for each language. Tamil data has been tokenized at word-level using *Indic-NLP* (Kunchukuttan, 2020) and then tokenized with BPE with 16 thousand operations.

Table 2 show the statistics for the parallel Englist-Tamil data as well as the monolingual corpora used.

As test set, we used 1275 lines extracted from the development set provided from the organization, keeping the remaining ones as validation set.

5 System Description

In this section, we are going to discuss the details of the pipeline followed to create the translations systems for this submission, including the multilingual supervised pretraining and the unsupervised fine-tuning using monolingual corpora.

5.1 Multilingual Supervised Pretraining

Methodology. Following the proposed model in (Escolano et al., 2020), new languages can be added to the system without retraining the system, just using parallel data to one of the initial ones. In this work, we added Tamil using the provided parallel data to English. To train the new Tamil to English translation direction, a new Tamil encoder is added to the system with the previous English encoder frozen, to prevent the model from affecting the performance of the remaining pairs. Training with the

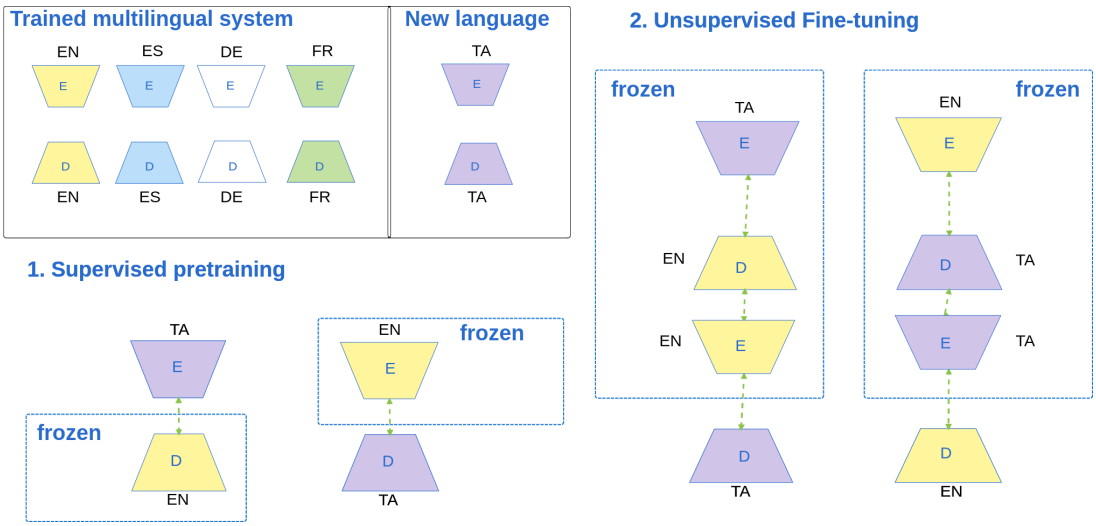

Figure 1: Training pipeline. Step 1 Supervised preptraining, Step 2 Unsupervised fine-tuning.

frozen decoder induces the new encoder to learn a similar representation to the ones already in the multilingual model. In addition, as the English decoder has been trained with more data from all the language pairs in the Multilingual NMT system, we have positive transfer from the frozen modules to the new ones, boosting the translation performance compared to the bilingual NMT baseline. Following the same principles, the English-Tamil translation direction is trained by freezing the English encoder and training the Tamil decoder to force the shared representation. In this case, we also notice the positive transfer compared to the baseline trained with just parallel data. See in Figure 1 the schema of the supervised pretraining that we have just described.

Implementation. For this work, all encoders and decoders were implemented using the Transformer (Vaswani et al., 2017) architecture, with 6 layers, 8 heads, 512 embedding size, and 2048 feed-forward size for each of them, and everything was implemented using *Fairseq*'s(Ott et al., 2019) 0.6 release. The multilingual NMT model was trained in a single NVIDIA TITAN XP for 50 thousand updates using adam optimizer with 0.001 as learning, 4000 warmup updates and updating every 16 batches of 2000 tokens. Adding Tamil-English and English-Tamil directions to the system took approximately 45 thousand updates using the same parameters and GPU configuration.

5.2 Monolingual Unsupervised Fine-tuning

Methodology. The previous process has benefited from the additional corpus from the Multilingual NMT system, but as stated before, monolingual data is another common source of improvement for NMT systems. In this section, we are going to discuss how we added monolingual data to the previously described model. To employ the monolingual data available in our system, we define an autoencoder using the already trained encoder and decoder modules in the given language. These modules are not trained to regenerate the input, we introduce an adaptor, between both modules, responsible for processing the representation generated and output a new one understood by the decoder. Taking advantage of the architecture, we can use one of the decoders to greedy decode the representation created and encode it back with one the encoders, to compute the reconstruction of the monolingual input. Figure 1 showcases in "unsupervised fine-tunning" how is process is applied in our work to use both Tamil monolingual data with an English adaptor and English data with the Tamil adaptor.

In this work, both encoder and adaptor were frozen, and only the final decoder was updated. As future work, then encoder could be also trained, improving the representations generated at each training epoch.

Implementation. As the rest of the architecture, this process has been implemented using the same GPU and parameter configuration, in this case for approximately 6 thousand updates.

5.3 Post-processing

Once our model is fully trained the apply an additional step of checkpoint averaging in which the n checkpoints containing the weights of the network are combined using the defaults script provided by *Fairseq*.

In this work, given that the corpus was small we saved checkpoint every epoch of approximately 400 updates and averaged the last 4 checkpoints saved.

Finally, to generate the final submissions, detruecasing and detokenization using the scripts provided by Moses to the English outputs, while IndicNLP detokenization is applied to the Tamil ones.

6 Experiments and Results

The motivation for this work was to explore the combination of both positive transfer and monolingual data in a low resource task such as English-Tamil Translation.

To test our hypothesis we trained a bilingual baseline with just the parallel data available for the task and compared its results to an incremental using adaptation to a multilingual NMT system and monolingual fine-tuning to measure the impact of each measure in the final performance. All configurations have the same architecture and number of parameters and have been tested on the same 1275 lines extracted from the *newsdev2020* Tamil-English set.

To introduce some context about the multilingual system, we evaluated its performance using *newstest13* as test set, and the performance English performance ranged from 20.31 BLEU points from the English-German translations direction, to 29.74 for English-French. When English is the target language the results vary from 24.54 for German-English, to 27.75 for Spanish-English. About the impact of positive transfer from Multilingual NMT, Tables 4 and 3 show that both directions benefit from adding Tamil into the MNMT system with improvement of 1.58 and 4.09 BLEU points respectively, approximately a 40% better than the bilingual baseline in both directions.

When looking at the monolingual fine-tuning results, we can observe that the English to Tamil translation direction benefits more (2.65 BLEU) from the technique than the Tamil to English direction (1.02 BLEU). This difference in the performance may be explained by the difference in the training of both decoders. While the Tamil decoder has been trained just with the parallel data for the task, the English decoder was trained with the multilingual NMT system with more data available, which may lead to a more robust model to fine-tuning.

Finally, looking at the checkpoint averaging results, in both directions it leads to a small improvement, less than 0.2 BLEU, showing limited impact in the final results.

System	BLEU	ΔBLEU
Baseline	3.42	-
Multilingual	5.00	1.58
+ Mono	7.65	2.65
+ Checkpoint Avg	7.92	0.27

7 Conclusions

In this paper, we described the TALP-UPC participation in the WMT20 news translation shared task for Tamil-English. The motivation of this work was to explore the combination of multilingual transfer from high resource languages and monolingual data applied to low resource NMT. Our experiments showcase the effectiveness of adapting low resource languages pre-trained multilingual systems and how it introduces positive transfer compared to a bilingual baseline system. Also it shows that monolingual data can be successfully introduced into the system and that it can boost the performance of the system. As future work, we could explore the fine-tuning of both encoder and decoder during the monolingual unsupervised fine-tuning in order to help the system produce better synthetic data as the training takes place.

An Iterative Knowledge Transfer NMT System for WMT20 News Translation Task

Jiwan Kim, Soyoon Park, Sangha Kim, Yoonjung Choi
Individual Researchers
{jiwan.kim37,parksso0223,shkim000,choiyj35}@gmail.com

Abstract

This paper describes our submission to the WMT20 News translation shared task in English to Japanese direction. Our main approach is based on transferring knowledge of domain knowledge and linguistic characteristics by pre-training the encoder-decoder model with large amount of in-domain monolingual data through unsupervised and supervised prediction task. We then fine-tune the model with parallel data and in-domain synthetic data which is generated by iterative back-translation. For additional gain, we generate final results with an ensemble model and re-rank them with averaged models and language models. Through these methods, we achieve +5.42 BLEU score compared to the baseline model.

1 Introduction

This paper describes our submission to the WMT20 News translation task in English to Japanese direction. In this year, English-Japanese directions have newly established in News Translation Shared Task. The English-Japanese translation is not easy to deal with because of the difference in word order and the rich morphological characteristics of Japanese. Nevertheless, recent architectures for Neural Machine Translation (NMT), such as Transformer (Vaswani et al., 2017), show reasonable results when we have enough parallel data. Unfortunately, however, there is not much in-domain parallel data provided for English-Japanese task. To solve this issue, in this paper, we suggest the iterative knowledge transfer system which pre-trains the model with in-domain monolingual data.

Our system is based on Transformer architecture. We pre-train the model to transfer linguistic characteristics and domain knowledge of monolingual data. Although there are various pre-training methods for NMT, MASS (Song et al., 2019) is adopted in our system since MASS pre-trains the encoder and the decoder jointly and uses both labeled data and unlabeled data as the training data. To supplement insufficient in-domain parallel data, we generate synthetic data by back-translation from in-domain monolingual data. We also add some noise to the synthetic data. We then pre-train the model with the synthetic parallel data for supervised method and the monolingual data for unsupervised way. In fine-tuning step, we train the model with parallel corpus and perform the back-translation with in-domain data for iterative fine-tuning. In addition, we adopt an ensemble and averaging methods which are simple but very effective to improve performance in deep learning. With ensemble and average models, we apply noisy channel re-ranking which shows higher performance compared to R2L re-ranking (Yee et al., 2019). Through these methods, we achieve +5.42 BLEU score (Papineni et al., 2002; Post, 2018) compared to the baseline model.

2 Approach

Our system aims to encourage knowledge extraction of domain knowledge and linguistic characteristics by iteratively performing pre-training and fine-tuning. In this section, we explain techniques we use in each step.

2.1 Pre-training strategy

MASS is a masked sequence to sequence pre-training method for the encoder-decoder based language generation tasks (Song et al., 2019). The advantage of MASS is that it uses the encoder-decoder framework to predict the masked part given the masked sentence. Several consecutive tokens in a sentence are randomly masked; the encoder takes them as input, and the decoder is trained to predict masked tokens. This method allows MASS to learn the capability of representation

Proceedings of the 5th Conference on Machine Translation (WMT), pages 139–144

extraction. In this paper, we adopt both supervised and unsupervised prediction methods of MASS. There are plenty of in-domain monolingual corpus but insufficient in-domain parallel corpus. Thus, we generate synthetic data by back-translation and apply supervised prediction task. In addition, we use large amount of out-domain monolingual corpus for unsupervised prediction task to encourage the ability of language modeling.

Let $x \in \mathcal{X}$ as an monolingual source sentence, and m is the number of tokens of sentence x. We denote $x^{\setminus u:v}$ as an modified sentence of x where its position u to v are masked, $0 < u < v < m$. $x^{u:v}$ denotes the original sentence fragment of x from u to v. Those sentences can have different fragment positions u and v for each. In the sentence fragment, we replace each masked token to a special symbol $[\mathbb{M}]$, so the number of words in the sentence is not changed. Then, we train model with the masked sentence $x^{\setminus u:v}$ to predict the sentence fragment $x^{u:v}$. Supervised setting is used also where bilingual sentence pair $(x, y) \in (\mathcal{X}, \mathcal{Y})$ can be leveraged for pre-training. It is trained to predict y from the input $x^{\setminus u:v}$. The log likelihood in the entire setting is as follows:

$$
\begin{aligned}
L(\theta; (\mathcal{X}, \mathcal{Y})) &= \frac{1}{|\mathcal{Y}|} \sum_{(x,y)\in(\mathcal{X},\mathcal{Y})} \log P(y|x^{\setminus u:v}; \theta) \\
&+ \frac{1}{|\mathcal{X}|} \sum_{(x,y)\in(\mathcal{X},\mathcal{Y})} \log P(x|y^{\setminus u:v}; \theta) \\
&+ \frac{1}{|\mathcal{X}|} \sum_{x\in\mathcal{X}} \log P(x^{u:v}|x^{\setminus u:v}; \theta) \\
&+ \frac{1}{|\mathcal{Y}|} \sum_{y\in\mathcal{Y}} \log P(y^{u:v}|y^{\setminus u:v}; \theta)
\end{aligned} \tag{1}
$$

$P(y|x^{\setminus u:v}; \theta)$ and $P(x|y^{\setminus u:v}; \theta)$ denote the probability of translating a masked sequence to another language. This prediction task encourages the encoder to extract meaningful representations of masked input tokens in order to predict the unmasked output sequence.

2.2 Noised back-translation

Inspired from the noised back-translation (Edunov et al., 2018; Wu et al., 2019), we add noise to the train corpus. Let X and Y denote two languages, and let $\mathcal{X}$ and $\mathcal{Y}$ denote two corresponding sentence corpora, a set of all sentences. Let $\mathcal{B} = \{(x_i, y_i)_{i=1}^{N}\}$ denote the bilingual training corpus, where $x_i \in \mathcal{X}$, $y_i \in \mathcal{Y}$, and N is the number of sentence pairs. Let $\mathcal{M}_x = \{x_j\}_{j=1}^{N_x}$ and $\mathcal{M}_y = \{y_j\}_{j=1}^{N_y}$ denote sets of monolingual sentences, where N_x and N_y are sizes of each set, $x_j \in \mathcal{X}, y_j \in \mathcal{Y}$. We then train models $f_b : \mathcal{X} \mapsto \mathcal{Y}$ and $g_b : \mathcal{Y} \mapsto \mathcal{X}$ on the given bilingual data $\mathcal{B}$. Then, we build the following two synthetic datasets through the trained models:

$$
\begin{aligned}
\bar{\mathcal{B}}_{sx} &= \{(x, f_b(x))|x \in \mathcal{M}_x\}, \\
\bar{\mathcal{B}}_{sy} &= \{(y, g_b(y))|y \in \mathcal{M}_y\}, \\
\bar{\mathcal{B}}_{tx} &= \{(f_b(x), x)|x \in \mathcal{M}_x\}, \\
\bar{\mathcal{B}}_{ty} &= \{(g_b(y), y)|y \in \mathcal{M}_y\}
\end{aligned} \tag{2}
$$

where $\bar{\mathcal{B}}_{sx}$, $\bar{\mathcal{B}}_{sy}$ can be seen the forward translation of source-side monolingual data of X and Y and $\bar{\mathcal{B}}_{tx}$, $\bar{\mathcal{B}}_{ty}$ can be seen the backward translation of target-side monolingual data of X and Y.

We build following noise versions of the augmented datasets for training.

$$
\begin{aligned}
\bar{\mathcal{B}}^n_x &= \{(\sigma(x), \sigma(y))|(x, y) \in (\bar{\mathcal{B}}_{sx} \cup \bar{\mathcal{B}}_{ty})\}, \\
\bar{\mathcal{B}}^n_y &= \{(\sigma(y), \sigma(x))|(y, x) \in (\bar{\mathcal{B}}_{sy} \cup \bar{\mathcal{B}}_{tx})\}
\end{aligned} \tag{3}
$$

where $\sigma(x)$ denote the noised sentence of x, which consists of two types of noise: deleting tokens with probability 0.05 and swapping tokens in the sentence, implemented as a random permutation over the tokens with the uniform distribution but restricted to swapping words no further than three positions apart, where three is set empirically.

2.3 Noisy channel re-ranking

Noisy channel re-ranking method (Yee et al., 2019) is derived from Bayes' rule.

$$
p(y|x) = \frac{p(x|y)p(y)}{p(x)} \tag{4}
$$

Let x as a source sequence and y as a target sequence. Since $p(x)$ is constant for all y, only the channel model $p(x|y)$ and the language model $p(y)$ determine y when x is given. Score used for re-ranking can be calculated as follows:

$$
\frac{\alpha * logp(y|x) + \beta * logp(x|y) + \gamma * logp(y)}{|y|^p} \tag{5}
$$

where α, β, γ are tunable weight, and p is length penalty for target length $|y|$.

3 Experiments

3.1 Data

Data statistics The training data of the entire system is shown in Table 1. We use News Commentary (NC) data as another validation set in addition to newsdev2020 (devset).

Dataset	Lines
Parallel Data	
Wiki_Titles v2	0.7M
WikiMatrix	3.89M
Japanese-English Subtitle Corpus	2.8M
The Kyoto Free Translation Task	0.44M

News Discussions	63.51M
Monolingual Data (Ja)	
News Crawl	3.44M
News Commentary v15	2983
Common Crawl	1773.97M

Table 1: Training corpora for our system

Preprocessing We use recaser in Moses (Koehn et al., 2007) to recase Japanese-English Subtitle Corpus where English side is lowercased. We also normalize punctuation marks and tokenize English corpus with Moses. We use Mecab (Kudo, 2006) to tokenize Japanese corpus. We adopt Sentencepiece (Kudo and Richardson, 2018); separate vocabs with 32K tokens are generated for each language. Separate vocabs show higher score in BLEU than a joint vocab in English-Japanese.

Filtering We first filter the parallel corpus based on length; sentences with more than 800 characters are removed from the training data. We then filter the training corpus with LangId (Lui and Baldwin, 2012). If LangIds of source or target side are mismatched, we filter out this data.

Data selection Unlike English, there are not enough news data in Japanese, so we select data from Common Crawl and use them as in-domain data. To obtain data close to in-domain, we classify sentences into in-domain and out-domain based on the perplexity of in-domain and out-domain language model (Moore and Lewis, 2010).

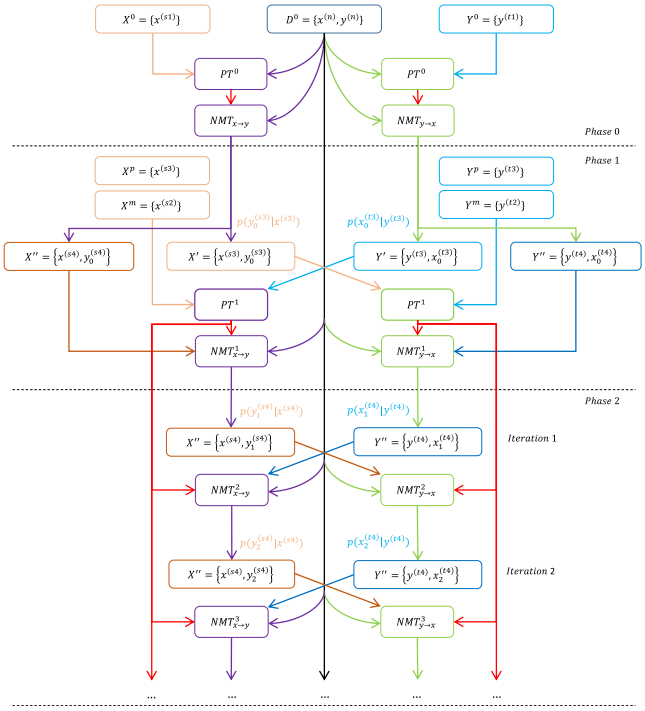

Figure 1: Illustration of training sequences of our system, where pre-trained models PT^* on both side are identical but separated for clarity.

Let $PPL_{in}(s)$ as the perplexity for sequence s with the in-domain language model and $PPL_{out}(s)$ as same with the out-domain language model. To classify sentences as close to in-domain, We calculate a score as follows:

$$\mathcal{S} = PPL_{out}(s) - PPL_{in}(s) \quad (6)$$

We train in-domain and out-domain language models respectively with KenLM (Heafield, 2011). The in-domain language model is trained with News Crawl corpus and the out-domain language model is trained with Common Crawl corpus.

3.2 Experimental setting

Our system is based on Transformer-big model on Fairseq (Ott et al., 2019)[1], which consists of 6-layers encoder and decoder each with 1024 embedding & hidden size and 4096 feed-forward layer size. Our system is trained using MASS[2] on 16×V100 GPUs, both in pre-training and fine-tuning.

3.3 Pre-training

Our entire training sequence is described in Figure 1. For the phase 0, we randomly sample 10M

[1] https://github.com/pytorch/fairseq
[2] https://github.com/microsoft/MASS

sentences X^0 and Y^0 from each mono corpus for unsupervised prediction task and use all available parallel corpus D^0 for supervised task. We prepare two separated prediction tasks, supervised and unsupervised setups respectively. For the supervised setup, we randomly mask entire input tokens in each sentence by 30% probability. In the unsupervised setup, we mask the fragment by replacing consecutive tokens with symbol $[\mathbb{M}]$ from random start position u. It first chooses 30% from input tokens, and each i-th token will be replaced as (1) an unchanged i-th token by 80% of the time, (2) a random token by 10% of the time, and (3) a masked token $[\mathbb{M}]$ by 10% of the time. After pre-training of model PT^0, two fine-tuned models $NMT_{x\to y}$ and $NMT_{y\to x}$ are trained with the parallel corpus, English-Japanese and Japanese-English direction respectively.

Lang	Lines	Remark

ja	20M	
ja*-en	5M	Randomly filtered
en*-ja	5M	LM-based filtered

Table 2: An amount of training corpora for pre-training. * means back-translated data from correspond monolingual corpus.

In the beginning of next phase, we create a new setup and train the model with training data mentioned in Table 2. We add noised synthetic data X' and Y' to create following version of training data. It consists of $\bar{\mathcal{B}}_{sx}$, $\bar{\mathcal{B}}_{sy}$, $\bar{\mathcal{B}}^n_x$ and $\bar{\mathcal{B}}^n_y$. X^m and Y^m consist of 20M mono corpora for unsupervised pre-training. 5M English mono corpus are randomly chosen from mono corpus, and 5M Japanese mono corpus are selected based on Equation 6; they are represented as X^p and Y^p in Figure 1. Then, 5M mono corpora are translated with $NMT_{x\to y}$ and $NMT_{y\to x}$ respectively.

PT^1 model is trained with above train corpus. Then, we train two fine-tuned models, $NMT^1_{x\to y}$ and $NMT^1_{y\to x}$ separately with parallel corpora in Table 3.

3.4 Iterative fine-tuning

After pre-training in phase 1, we create fine-tuned models with parallel corpus D^0 and synthetic corpus X'' and Y''.

Inspired from joint training (Zhang et al., 2018), we perform back-translation and fine-tune steps iteratively in phase 2. Synthetic corpora for each steps are replaced to a newly generated ones from developed models, which are represented as X'' and Y'' in Figure 1.

			Japanese - English
ja-en	7M	out	
ja*-en	7M	in	Randomly filtered

Table 3: An amount of training corpora for fine-tuning

3.5 Advance decoding

We improve our final result with noisy channel re-ranking method (Yee et al., 2019). The small difference is we use the different direct model for scoring instead of using the same model used for generation. To generate y, we first ensemble three models with final back-translated models, considering validation sets. We generate 44 n-bests results with 44 beam size with ensemble models. Then, we re-rank the results according to Equation 5. The direct model for scoring is the averaged model of three models used for ensemble. This is faster and shows better results compared to the ensemble model. The channel model is an average model in the opposite direction. For language model, we use Transformer-big model, trained only with News domain monolingual corpus. Finally, we tune weights of each model and length penalty with validation sets.

Model	Test
Baseline	20.51
Ensemble + Beam 44	25.05
Re-ranking(devset)	24.41
Re-ranking(NC)	**25.93**

Table 5: En-Ja BLEU scores on WMT20 test set.

The results of English to Japanese direction are shown in Table 4 and 5. Our final submission's BLEU score is 5.42 higher than the baseline model.

For evaluation, multi-bleu.perl[3] is used after tokenizing with Mecab in Japanese. The baseline model is trained only with parallel data in Transformer-big architecture and is decoded with beam size 4. It shows great performance improvement when MASS is applied. When using synthetic data and adding noise to data in pre-training steps (Phase 1), it shows better results compared to it with only parallel data (Phase 0). Back-translation with the in-domain monolingual data increases the BLEU score most, and the score increases further in the next iteration. The ensemble model and large beam size also show better BLEU score.

For the test set, we replace symbol £ to "pound" in source sentences as pre-processing. We re-rank and tune the parameters based on News Commentary parallel data set which shows better results than tuning with devset. Since we select best models based on devset in previous steps, using devset in re-ranking seems to result in overfitting.

The final result of our submission is shown in Table 6. Characters based tokenizer and SacreBLEU[4] are used for evaluation in Ocelot.

Submission	SacreBLEU	chrF
English-Japanese	41.0	0.351

Table 6: Automatic evaluation on WMT20 test set in Ocelot.

4 Conclusions

In this paper, we describe our submission to the WMT20 news translation task in English to Japanese direction. Our main approach is based on transferring knowledge from large amount of monolingual data by pre-training the model iteratively using MASS. We then improve the system with several effective methods: noised and iterative back-translation, in-domain data selection, and re-ranking. Through these methods, we achieve competitive results compared to the baseline and prove that the iterative knowledge transfer system we proposed is effective.

Abstract

In this paper, we describe the submission of Tohoku-AIP-NTT to the WMT'20 news translation task. We participated in this task in two language pairs and four language directions: English↔German and English↔Japanese. Our system consists of techniques such as back-translation and fine-tuning, which are already widely adopted in translation tasks. We attempted to develop new methods for both synthetic data filtering and reranking. However, the methods turned out to be ineffective, and they provided us with no significant improvement over the baseline. We analyze these negative results to provide insights for future studies.

1 Introduction

The joint team of Tohoku University, RIKEN AIP, and NTT (Tohoku-AIP-NTT) participated in the WMT'20 shared news translation task in two language pairs and four language directions: English→German (En→De), German→English (De→En), English→Japanese (En→Ja), and Japanese→English (Ja→En).

At the very beginning of this year's shared task, we planned to employ the following two enhancements at the core of our system. The first enhancement is the noisy synthetic data filtering (Koehn et al., 2018) to better utilize the millions of back-translated synthetic data. However, as we analyze in Section 5.1, this filtering turned out to be ineffective. The second enhancement is the reranking of n-best candidates generated a the model.

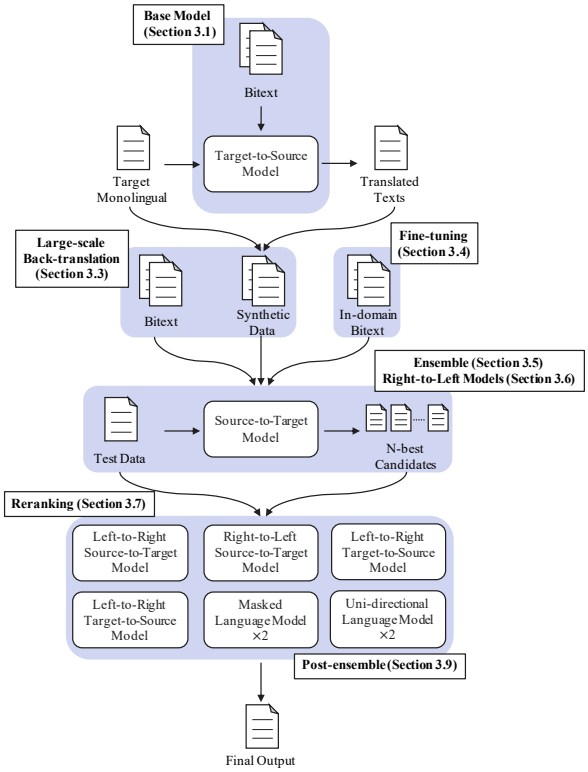

Figure 1: Overview of our system.

Given a collection of scores from multiple generative/translation models, our reranking module selects the best candidate. We attempted to develop sophisticated machine learning based methods for optimizing the weight of each score. However, we found that those methods are not as effective as the simple grid search on the BLEU score (details in Section 3.7 and Section 5.3).

Eventually, we designed our system as a combination of techniques that are already widely adopted in the shared task, such as back-translation and fine-tuning. The overview of our system is shown in Figure 1. We achieved the first place in De→En on automatic evaluation and obtained strong results in other language directions.

[*] Shun conducted most of the experiments for both En↔De and En↔Ja. Takumi preprocessed En↔Ja data. Ryuto trained fasttext word vectors and implemented the post-ensemble method. Takumi and Ryuto worked on synthetic data filtering approaches. Makoto back-translated monolingual corpus for all language directions. Shun, Makoto, and Takumi developed an effective fine-tuning strategy. Jun implemented the entire reranking module and organized the team. Everyone contributed to writing this paper.

Online, November 19–20, 2020.

2 Dataset and Preprocessing

2.1 Bitext

For both En↔De and En↔Ja, we used all bitexts that are available for a constrained system.

En↔De Following Ng et al. (2019), we applied language identification filtering (`langid`)[1] to the bitext. In this filtering, sentence pairs were removed if a supposedly English/German sentence is identified as a non-English/German sentence. Then, we applied the `clean-corpus-n` script available in the Moses toolkit (Koehn et al., 2007) and removed sentence pairs that are either too long and/or their length ratio is too large[2]. These two filtering processes provided us with approximately 44M sentence pairs. Then, we trained and applied the Moses `truecaser` independently for each language. We also trained byte-pair encoding (BPE) (Sennrich et al., 2016c) models using the `sentencepiece` (Kudo and Richardson, 2018) implementation. For BPE training, we used only a subset of the parallel corpus (Europarl, NewsCommentary, and RAPID) to prevent extremely rare characters from contaminating the vocabulary and the subword segmentation.

En↔Ja Similar to En↔De, we applied `langid` to clean bitext, but we did not use `clean-corpus-n` since the Japanese text is not segmented. Instead, we simply removed sentence pairs in which the English sentence is longer than 500 tokens. Eventually, we obtained about 17M sentence pairs. We used `truecaser` for the English side only, because case information does not exist in the Japanese language. We independently trained the BPE merge operation on the bitext. We set the character coverage option[3] of `sentencepiece` to 1.0 and 0.9998 for English and Japanese, respectively.

2.2 Monolingual Corpus

The origins of the monolingual corpus in our system are the Europarl, NewsCommentary, and entire NewsCrawl (2008-2019) corpora for English and German, and the Europarl, NewsCommentary and CommonCrawl corpora for Japanese. Similarly to bitext preprocessing in Section 2.1, we applied `langid` filtering to all monolingual corpora. These corpora are used for large-scale back-translation (Section 3.3).

3 System Overview

3.1 Base Model and Hyperparameter

The well-known Transformer model (Vaswani et al., 2017) is our base Encoder Decoder model. Specifically, we started with the "Transformer (big)" setting described by Vaswani et al. (2017) and increased the feed-forward network (FFN) size from 4,096 to 8,192. Ng et al. (2019) reported that this larger FFN setting slightly improves the performance; we also confirmed it in our preliminary experiment.

Table 1 shows a list of hyperparameters for model optimization. We employed an extremely large mini-batch size of 512,000 tokens using the delaying gradient update technique (Bogoychev et al., 2018; Ott et al., 2018). This is because previous studies showed that a large mini-batch size leads to a faster convergence (Ott et al., 2018) and a better generalization (Popel and Bojar, 2018; Bawden et al., 2019; Morishita et al., 2019). We also used a large learning rate of 0.001 to further accelerate the convergence (Goyal et al., 2017; Ott et al., 2018; Liu et al., 2019). We use the `fairseq` toolkit (Ott et al., 2019) for the entire set of experiments. Every reported BLEU score is measured using `SacreBLEU` (Post, 2018).

3.2 Subword Size

For En↔De, we used the subword size of 32,000, which is commonly used in previous studies (Vaswani et al., 2017; Ng et al., 2019). For En↔Ja, we conducted a hyperparameter search for a suitable subword size; Morishita et al. (2019) empirically showed that a small subword size (e.g., 4,000) is superior to those commonly adopted in the literature (e.g., 16,000 and 32,000). Given their findings, we searched for the subword size in the following range: {4000, 8000, 16000, 32000}.

Table 2 shows that the largest subword size achieves the best performance, which is inconsistent with the result of Morishita et al. (2019). One explanation for this result is that Morishita et al. (2019) conducted an experiment on the ASPEC corpus, whose size (approx. 3M) is much smaller than that of the bitext available for the En↔Ja task. That is, the bitext available for the En↔Ja task is sufficiently large for the model to learn a meaningful representation for each subword unit that is

[1] https://github.com/saffsd/langid.py

[2] We set the minimum length to 1, the maximum length to 250, and the maximum ratio to 3.0.

close to the word level. Thus, we also used the subword size of 32,000 for En↔Ja.

3.3 Large-scale Back-translation

We used the back-translation technique (Sennrich et al., 2016b) to generate large-scale synthetic data. First, we trained models on the bitext for all language pairs. Second, for each language, we fed the monolingual corpus (Section 2.2) to the model. Here, we used the beam search of width 6 and length penalty of 1.0. Finally, we applied length and ratio filtering to the model outputs[4]. The size

[4]For En↔De, we removed sentence pairs that contain sentences longer than 250 tokens. For En↔Ja, we removed sentence pairs such that the English sentence is longer than 250 tokens, or the Japanese sentence is longer than 500 characters.

Subword Size	En→Ja
4,000	19.2
8,000	19.6
16,000	19.4
32,000	19.7

	En→De	De→En	En→Ja	Ja→En
No filtering	336M	236M	1777M	236M
After filtering	328M	230M	235M	230M

Table 3: Number of sentence pairs in the synthetic data of each language pair

of the synthetic data that we generated for each language direction is shown in Table 3. The size of the synthetic data for En→Ja, which is generated from CommonCrawl, is extremely large. Thus, we randomly subsampled the synthetic data of En→Ja so that its size roughly matches those of De→En and Ja→En.

We searched for an effective setting for incorporating the synthetic data. As the most straightforward starting point, we simply combined bitext and synthetic data and trained the model. Here, we upsampled the bitext so that the model sees the bitext and synthetic data at a 1:1 ratio (Ng et al., 2019). Table 4 shows the result. Here, naively using the synthetic data (BASE+BT) decreased the performance of the model trained with the bitext only (BASE). Given this result, we considered the following two enhancements:

Tagged Back-translation We used the tagged back-translation technique (Tagged-BT) (Caswell et al., 2019), which prepends a special tag token (e.g., ⟨BT⟩) to the source sentence of synthetic data. This simple technique can inform the model about the origin of the given training data, i.e., whether the sentence pair is back-translated. Marie et al. (2020) empirically demonstrated that the model trained with such tagged data can avoid overfitting to the synthetic data. In Table 4, the Tagged-BT (BASE+TAGGED-BT) successfully improves the performance from BASE except for the newstest2019. We suspect that the performance does not improve on newstest2019 because it does not contain the "translationese" text, i.e., human-generated translations, which are reported to be the main source of improvement of back-

Setting	newstest 2014	2018	2019
BASE	32.2	47.3	42.2
BASE+BT	32.1	45.9	38.8
BASE+TAGGED-BT	33.0	48.0	42.0
BASE ($l = 9$)+TAGGED-BT	33.1	49.6	42.7
BASE ($l = 12$)+TAGGED-BT	33.4	49.4	42.3

Table 4: Effectiveness of using the synthetic data on En→De

translation (Bogoychev and Sennrich, 2019; Marie et al., 2020).

Deeper Model We also considered increasing the model size to take advantage of a massive amount of training data. Specifically, we increased the number of layers l from 6 to 9 and 12 (Wang et al., 2019). Table 4 shows that the performances of BASE ($l = 9$)+TAGGED-BT and BASE ($l = 12$)+TAGGED-BT are almost comparable. We determined that BASE ($l = 9$)+TAGGED-BT is the best option by considering the model performance and training efficiency regarding the GPU memory constraints.

3.4 Fine-tuning

Fine-tuning the model with an in-domain news corpus is acknowledged as an extremely important technique for boosting the performance (Sennrich et al., 2016b; Junczys-Dowmunt, 2019; Ng et al., 2019; Bawden et al., 2019). We fine-tuned our models as follows:

En↔De For En↔De, we fine-tuned the model with a collection of newstest2008-2018 and evaluated its performance on newstest2019. For En→De, we only used sentence pairs whose source sentence is originally written in English, i.e., we never used texts with translationese on the source side for fine-tuning. Similarly, for De→En, we used sentence pairs whose source sentence is originally written in German. This way, we ensured that our model does not overfit to the translationese texts; since newstest2019 does not contain translationese texts (Barrault et al., 2019), we expected that newstest2020 does not contain translationese either.

We fine-tuned the model for 200 iterations with a mini-batch size of 20,000 tokens. During the fine-tuning, we fixed the learning rate to 1e-06 for De→En and 1e-05 for En→De. We saved the model every 20 iterations and took an average of the last eight saved models for decoding.

En↔Ja For fine-tuning, we used the Kyoto Free Translation Task (KFTT) corpus and NewsCommentary as the *clean* bitext and NewsCommentary as the *news* bitext. We fine-tuned the models by a two-step procedure, that is, we first fine-tuned with the *clean* bitext for 2,000 steps. Then we fine-tuned with the *news* bitext for 200 steps. We found that the validation performance of this two-step procedure is slightly better than that of the fine-tuning with the *news* bitext only.

3.5 Ensemble

We used the model ensemble method to improve the performance. First, we trained four models with different random seeds. These models were then simultaneously used for computing the score of each candidate during the beam search decoding.

3.6 Right-to-Left Models

We used Right-to-Left (R2L) models for reranking the n-best candidates from Left-to-Right (L2R) models. R2L models generate sentences in reverse order. Suppose that conventional L2R models generate sentences from the beginning-of-the-sentence (BOS) to the end-of-the-sentence (EOS); R2L models generate from EOS to BOS. This reranking technique was independently proposed by Liu et al. (2016) and Sennrich et al. (2016a) to mitigate the search error of L2R models, which may occur around EOS. We trained four R2L models and used their scores for reranking the n-best candidates generated by L2R models (Section 3.5). Specifically, we computed the score of each candidate with both L2R models and R2L models. Then, we took the sum of the two scores and obtained the final score. We sorted this final score and then selected the candidate with the highest score.

3.7 Reranking

We also applied a reranking method based on the scores of several translation (or generative) models, which is closely related to one iteration of Minimum Error Rate Training (MERT) (Och, 2003) often used in Statistical Machine Translation (SMT). The underlying idea is to find the balance of likelihood independently computed from the models.

Suppose we have a set of candidate output sentences for each input in either the validation (training phase) or the test (evaluation phase) sets. In our case, we independently generated n-best candidates using the L2R and R2L models, and obtained $2n$ candidates in total for each. Here, let $\mathcal{C}_i$ represent the set of the obtained $2n$ candidates of the

i-th input.

Next, $P_j(e) \in [0, 1]$ denotes the score of the candidate $e \in \mathcal{C}_i$ obtained from the j-th model, where $j \in \{1, \ldots, J\}$. Let $w_j \in [0, 1]$ be a weighting factor of the j-th model, and $\boldsymbol{w} = (w_1, \ldots, w_J)$ be the vector representation of the weighting factor. We then obtained the most likely candidate $\hat{e}_{i,\boldsymbol{w}}$ from $\mathcal{C}_i$ given the i-th input and $\boldsymbol{w}$ as follows:

$$\hat{e}_{i,\boldsymbol{w}} = \underset{e \in \mathcal{C}_i}{\operatorname{argmax}} \left\{ \sum_{j=1}^{J} w_j \log(P_j(e)) \right\}. \quad (1)$$

Finally, for the parameter estimation of $\boldsymbol{w}$, we explored $\widehat{\boldsymbol{w}}$ by using the following optimization problem:

$$\widehat{\boldsymbol{w}} = \underset{\boldsymbol{w} \in \mathcal{G}_{\boldsymbol{w}}}{\operatorname{argmax}} \{ \texttt{SacreBLEU}(\widehat{\mathcal{E}}_{\boldsymbol{w}}) \}, \quad (2)$$

where $\hat{\mathcal{E}}_{\boldsymbol{w}} = (\hat{e}_{i,\boldsymbol{w}})_{i=1}^{I}$ and $\mathcal{G}_{\boldsymbol{w}}$ represent a set of values that w_j can take, namely, $[0, 1]^J$.

For the reranking experiment, we prepared the following generative and translation models to compute $P_j(e)$.

Source-to-Target L2R and R2L Model The Source-to-Target L2R and R2L models are the same as that used for the candidate generation; the ensemble of four L2R models and four R2L models compute the score of each candidate.

Target-to-Source L2R and R2L Model The Target-to-Source (T2S) model translates a sequence in a reverse direction, that is, it translates a given target sequence to a source sequence. For example, if a candidate sentence is generated by the En→De model, we use the De→En model for computing the T2S score.

Uni-directional Language Model We used the uni-directional language model (UniLM) to compute the likelihood of the decoded target sequence. To do this, we trained the Transformer-based language model (Baevski and Auli, 2019) for all languages on monolingual data. We obtained two distinct scores from two normalization methods: (1) simply dividing by the target sequence length (Yee et al., 2019) and (2) *SLOR* (Pauls and Klein, 2012; Lau et al., 2020). A list of hyperparameters is shown in Table 1.

Masked Language Model We also used the pretrained masked language model (MLM) (Devlin et al., 2019) for computing the score. Specifically, we trained the RoBERTa-base (Liu et al., 2019) setting available in `fairseq` on monolingual data. First, we computed the unnormalized log-probabilities by the method described by Wang and Cho (2019). Then, we normalized the probability by (1) dividing by the sequence length and (2) *PenLP* (Vaswani et al., 2017; Lau et al., 2020). A list of hyperparameters is shown in Table 1.

Because the uni-directional language model and MLM both have two distinct variations, we used a total of six models, namely, $J = 6$.

3.8 Post-processing

We converted the decoded target sequence from a sequence of subwords to tokens. Then we applied the Moses `detruecaser` to English and German sequences. We also applied language-specific post-processing as follows:

En↔De We observed that the rare tokens such as Greek letters in the source sequence are sometimes translated into ⟨UNK⟩. We handled ⟨UNK⟩ in the decoded sequence by copying the corresponding token from the source sequence. We determined the corresponding token by finding the token that does not exist in one of the source-side or target-side vocabularies.

En→Ja We did not take any special measures for ⟨UNK⟩[5]. We replaced the English style comma ", " and period ". " with the Japanese style "、" and "。" respectively.

Ja→En We observed that the model translates the Japanese vertical bar " ｜ " to ⟨UNK⟩. Thus, we replaced all ⟨UNK⟩ with "|".

3.9 Post-ensemble

Kobayashi (2018) proposed the method of taking the ensemble of multiple models *after* decoding the sequence, namely, post-ensemble (POSTENSEMBLE). The underlying idea of POSTENSEMBLE is to choose "majority-like" candidates by comparing the similarities among candidates. He applied POSTENSEMBLE to the abstractive summarization task and reported that the performance is superior to that of the conventional ensemble.

We used POSTENSEMBLE in En→Ja[6]. Specifically, we adopted the `PostCosE` variant in which the cosine similarity is used as a similarity metric. We created 300 dim fasttext word vectors (Bojanowski et al., 2017) on the Japanese monolingual corpus.

[5] In fact, we never observed ⟨UNK⟩ in the decoded test set.

[6] Kobayashi (2018) introduced POSTENSEMBLE as the method that *replaces* the conventional ensemble. Instead, we used two ensemble methods simultaneously.

4 Results

Performance on the Validation Set We show the validation performance of our system in Table 5. We used newstest2019 and the official validation set for En↔De and En↔Ja, respectively, for the validation data. The table shows the effectiveness of incorporating each technique described in Section 3. Each technique consistently improves the performance in most cases. In addition, it is noteworthy that both En→De and De→En models significantly outperform the performance of the best system from last year's shared task (WMT'19).

Performance on the Test Set We show the test set performance that we measured in the OCELoT system[7] in Table 6. The system provides us with the SacreBLEU score and the chrF score (Popović, 2015).

We used the following models for POSTENSEMBLE of Ja→En: (1) model (f) (Table 5), (2) Model (f) with the ensemble of eight models, in which four models are fine-tuned with the *clean* bitext and the other four models are fine-tuned with the *news* bitext, and (3) Model (2) without n-best candidates from the R2L model.

The performance of En→Ja appears significantly better than the validation performance reported in Table 5; this is because OCELoT computes the BLEU score with character-level segmentation, whereas we used the MeCab-based word-level segmentation[8]. We also computed the BLEU score with the MeCab-based segmentation for reference and obtained 25.8 points.

5 Analysis

In this section, we introduce several negative results from our preliminary experiments. Our attempts include the following: (1) filtering synthetic data, (2) incorporating forward-translation, and (3) developing a more sophisticated reranking method. We also analyze the issue regarding the use of brackets in the En→Ja task.

5.1 Negative Results on Synthetic Data Filtering

We applied corpus filtering to the synthetic data created in Section 3.3. The goal of this filtering is to extract and utilize the "clean" subset of synthetic data that may contribute to the model performance. For each of the sentence pairs in the synthetic data, we assigned scores that represent the likelihood of being a sentence pair (Section 5.1.1). Then, we regarded these scores as features for classification; we trained a model classifying clean and noisy sentence pairs (Section 5.1.2). Finally, on the basis of the confidence scores of the classifier, we extracted the presumably clean subset of the synthetic data.

5.1.1 Features

Pointwise HSIC We computed the score for each sentence pair using the pointwise Hilbert-Schmidt independence criterion (PHSIC) (Yokoi et al., 2018), which is a kernel-based co-occurrence measure. Given a set of sentence pairs, PHSIC can assign a high score to a sentence pair that is consistent with the rest of the sentence pairs. To do this, PHSIC utilizes kernel functions and calculates the sentence similarity. Yokoi et al. (2018) applied PHSIC to machine translation corpus filtering and reported promising results. Thus, we also employed PHSIC for synthetic data filtering.

First, we learned the parameters of the PHSIC matrix with a cosine kernel by using all sentence pairs in the bitext, which are represented as sentence embeddings. Then, we used this trained matrix to compute the scores for the synthetic data. We used the following two methods for computing the sentence embeddings: (1) the weighted sum of fasttext vectors (Bojanowski et al., 2017) by smoothed inverse frequency (SIF) weighting (Arora et al., 2017) and (2) the average of final hidden states of the pre-trained MLM. Here, the fasttext vector is the same as the one used for post-ensemble (Section 3.9), and MLM is the one from the reranking (Section 3.7). The word frequency for SIF weighting is calculated from the monolingual corpus.

Cross-entropy from T2S Model We computed the word-normalized conditional cross-entropy using the T2S translation model. For example, the synthetic data generated using the En→De model are scored using the De→En model.

5.1.2 Training a Classifier

We trained a linear support vector machine model that classifies clean and noisy sentence pairs. To train the classifier, we used newstest2009-2019 and the official validation set as clean sentence pairs for En↔De and En↔Ja, respectively. We generated the noisy sentence pairs by randomly adding the noise presented by Wang et al. (2018) to the clean sentence pairs.

[8] The use of the MeCab-based segmentation is recommended by SacreBLEU.

ID	Setting	En→De	De→En	En→Ja	Ja→En
(a)	BASE (Section 3.1)	42.4	42.0	19.7	21.6
(b)	BASE ($l = 9$)+TAGGED-BT (Section 3.3)	42.7	42.5	22.0	23.9
(c)	(b) + fine-tuning (Section 3.4)	44.9	42.3	23.1	24.4
(d)	(c) × 4 (Section 3.5)	45.5	42.8	23.9	25.4
(e)	(d) + 4 × (c)-R2L (Section 3.6)	45.4	43.6	24.2	25.9
(f)	(e) + reranking (Section 3.7)	45.7	43.8	24.9	26.2
-	The best system in WMT'19	44.9	42.8	-	-

Table 5: Effectiveness of each technique: we use newstest2019 and official validation set for En↔De and En↔Ja respectively. The best result from WMT'19 is unavailable for En↔Ja, because this task has newly appeared this year.

Direction	Setting / ID	BLEU	chrF
En→De	(f) (Table 5)	37.5	0.647
De→En	(f) (Table 5)	43.8	0.690
En→Ja	(f) (Table 5)	40.1	0.343
Ja→En	POSTENSEMBLE	25.5	0.536

Table 6: Performance on WMT'20 Test Set: refer to Table 5 for model ID.

After training, we classified each sentence pair in the synthetic data. The confidence score of the classifier was used as an overall score that represents the "cleanness" (i.e., quality) of the sentence pair.

5.1.3 Results

We investigated the effectiveness of the synthetic data filtering. First, we sorted the synthetic data according to the score computed with the classifier (Section 5.1.2). Then, we used the top $r\%$ of synthetic data for training.

Table 7 shows the results of synthetic data filtering with varying r. We trained the En→De model using the BASE+TAGGED-BT setting. The results showed that our filtering does not seem to improve the performance over the baseline ($r = 100$). One of the possible reasons for this ineffectiveness is the quality of the sentence embeddings used for PHSIC. That is, the use of fasttext and pretrained MLM might be inappropriate. Utilizing more powerful sentence encoders such as Sentence-BERT (Reimers and Gurevych, 2019) and Universal Sentence Encoder (Cer et al., 2018) is an interesting option to explore in the future; however, the methods of acquiring such resources in the constrained setting is not trivial.

	newstest		
Amount of Synthetic Data Used: r (%)	2014	2018	2019
100	33.0	48.0	42.0
50	32.9	48.4	42.3
33	33.1	47.9	42.2
25	32.9	48.5	42.4

Table 7: Effectiveness of corpus filtering on En→De.

	newstest		
Setting	2014	2018	2019
BASE	32.2	47.3	42.2
BASE+TAGGED-BT	33.0	48.0	42.0
BASE+TAGGED-FT	31.7	46.7	42.1
BASE+TAGGED-BT+TAGGED-FT	33.1	48.3	42.4

Table 8: Effectiveness of incorporating forward-translation and back-translation on En→De.

5.2 Effectiveness of Incorporating Forward-Translation

Forward-translation (Burlot and Yvon, 2018) is a technique similar to back-translation; the difference is that while back-translation uses the target-side monolingual data, forward-translation uses the source-side monolingual data to generate synthetic data. Bogoychev and Sennrich (2019) reported that forward-translation is effective for improving the translation of texts that are originally written in the source language (i.e., non-translationese texts).

To determine if we can take the best of the two techniques, namely, forward-translation and back-translation, we combined the synthetic data and trained the model. As described in Section 3.3, we prepended a distinct tag to each data source: ⟨FT⟩ and ⟨BT⟩ for data generated by forward-translation and back-translation respectively. Then, we upsampled the bitext, so that the model is fed with the bitext and synthetic data at a 1:0.5:0.5 ratio.

Table 8 shows the result. The model in-

Input	Only one member of the family, then 15-year-old Cassidy Stay, survived.
Reference	家族の中で、ただ一人、当時15歳だったカシディ・ステイさんだけが一命を取り留めた。
Model Output	当時15歳のキャシディ・ステイ(Cassidy Stay)だけが生き残った。
Input	Madam Needjan, pledged the association's support to the hospital and called on other associations to emulate the gesture.
Reference	マダム・ニージャンは、協会の当病院への支援を約束し、他の団体もこうした行為に追随するよう呼びかけた。
Model Output	マダム・ニージャン(Madam Needjan)は、協会が病院を支援することを約束し、他の協会にこのジェスチャーを模倣するよう求めた。

Figure 2: Error analysis of En→Ja translation.

corporating both back-translation and forward-translation (BASE+TAGGED-BT+TAGGED-FT) achieves the best result, however, the improvement was marginal. In addition, the performance of the model with forward-translation only (BASE+TAGGED-FT) was worse than that of the baseline (BASE) in all datasets. Given this result, we only used back-translation and kept the training procedure as simple as possible in our final system.

5.3 Negative Result on Reranking

We actually investigated several different types of reranking algorithms other than the standard grid search described in Section 3.7. For example, we experiment withed optimizing model weights by machine learning based methods such as those using support vector machines, XGBoost (Chen and Guestrin, 2016), and deep neural networks. Unfortunately, none of them worked well. In this competition, we only used the model scores for the reranking. This setting immediately leads the overfitting to the development sets, and hard to extract meaningful generalized weights (rules) that also work well for unseen test data. The development of the methods that can further and consistently improve the quality of translations is our future work for the next year.

5.4 Japanese Text and Brackets

Figure 2 shows examples from the validation set of the En→Ja task. These examples illustrate the weakness of our model, in which the named entities are often inappropriately translated. According to the references in the figure, the named entities must be translated from alphabetical characters to *katakana* (カタカナ), e.g., *Cassidy Stay* to カシディ・ステイ. Although our model successfully translates the named entities in most of the cases, the model also copies original alphabetical characters into the brackets. For example, the model translates *Madam Needjan* to マダム・ニージャン*(Madam Needjan)*. These alphabetical characters damage the BLEU score. We can remove the extra brackets by the rule-based post-processing; however, we find that this naive operation hurts the brevity penalty.

This extra bracket problem seems to reflect the way that the named entities are written in the En↔Ja training data such as KFTT. We should have considered special preprocessing measures in advance to alleviate this problem.

6 Conclusion

In this paper, we described the submission of the joint team of Tohoku, AIP, and NTT (Tohoku-AIP-NTT) to the WMT'20 news translation task. We participated in the En↔De and En↔Ja translation. In preliminary experiments, we attempted new techniques such as synthetic data filtering, forward-translation, and sophisticated reranking. However, none of them was effective. In the submission, we used several standard techniques such as back-translation and fine-tuning. As a result, we achieved the best BLEU score on De→En and strong results in other directions.

Acknowledgments

We would like to thank the two anonymous reviewers for their valuable feedback.

NRC Systems for the 2020 Inuktitut–English News Translation Task

Rebecca Knowles, Darlene Stewart, Samuel Larkin, and **Patrick Littell**
National Research Council Canada
{Rebecca.Knowles, Darlene.Stewart, Samuel.Larkin, Patrick.Littell}@nrc-cnrc.gc.ca

Abstract

We describe the National Research Council of Canada (NRC) submissions for the 2020 Inuktitut–English shared task on news translation at the Fifth Conference on Machine Translation (WMT20). Our submissions consist of ensembled domain-specific finetuned transformer models, trained using the Nunavut Hansard and news data and, in the case of Inuktitut–English, backtranslated news and parliamentary data. In this work we explore challenges related to the relatively small amount of parallel data, morphological complexity, and domain shifts.

1 Introduction

We present the National Research Council of Canada (NRC) Inuktitut–English[1] machine translation (MT) systems in both translation directions for the 2020 WMT shared task on news translation.

Inuktitut is part of the dialect continuum of Inuit languages, the languages spoken by Inuit, an Indigenous people whose homeland stretches across the Arctic. Included in this continuum are Indigenous languages spoken in northern Canada, including but not limited to the Territory of Nunavut. The term *Inuktut* is used by the Government of Nunavut (2020) to describe Inuit languages spoken in Nunavut, such as Inuktitut and Inuinnaqtun. The majority of the Inuit language text provided for the shared task comes from ᓄᓇᕗᑦ ᒪᓕᒐᓕᐅᕕ (Nunavut Maligaliurvia; Legislative Assembly of Nunavut) through the Nunavut Hansard, the published proceedings of the Legislative Assembly of Nunavut. The Nunavut Hansard is released publicly by the Government of Nunavut in Inuktitut and English (also an official language of Nunavut), and with their generous assistance was recently processed and released for use in building MT systems (Joanis et al., 2020).[2]

In this work, we examined topics related to morphological complexity and writing systems, data size, and domain shifts. Our submitted systems are ensembled domain-specific finetuned transformer models, trained using Nunavut Hansard and news data and, in the case of Inuktitut–English, backtranslated news and parliamentary data. We measured translation performance with BLEU (Papineni et al., 2002),[3] metrics specific to the production of Roman text in Inuktitut, and human evaluation (to be reported). We hope that human evaluation will provide insight as to whether the current state of the art is sufficient to start building computer aided translation tools of interest and use to Inuit language translators, or whether more work is needed to make the systems usable.

2 Related Work and Motivation

Initial experiments on building neural machine translation (NMT) systems for Inuktitut–English using the most recent Nunavut Hansard corpus are reported in Joanis et al. (2020). Earlier work includes Micher (2018) and Schwartz et al. (2020), and, predating the recent wave of NMT, Martin et al. (2003), Martin et al. (2005), and Langlais et al. (2005). There has also been work on morphological analysis of Inuktitut, including Farley

[1] Abbreviated `iu` and `en` using ISO 639-2 codes.

[2] Though we note that Inuktitut, Inuinnaqtun, English, and French may all be spoken in the House, we use the term Inuktitut in describing our MT systems for two main reasons: 1) the official website describes the Nunavut Hansard as being published "in both Inuktitut and English" (Legislative Assembly of Nunavut, 2020) and 2) because we wish to make clear the limitations of our work; there is no reason to expect that the systems built using the data provided for WMT will perform well across various Inuit languages and dialects (or even across a wider range of domains).

[3] Computed using `sacreBLEU` version 1.3.6 (Post, 2018) with mteval-v13a tokenization: `BLEU+case.mixed+numrefs.1+smooth.exp+tok.13a`.

Proceedings of the 5th Conference on Machine Translation (WMT), pages 156–170

(2009) and Micher (2017). In this work, we focus mainly on approaches that are not language-specific, but that are motivated by specific challenges of translating relatively low-resource, morphologically complex languages; thus they are also not entirely language-agnostic.

2.1 Language Typology and Writing Systems

Inuit languages are highly morphologically-complex; many Inuktitut words consist of a large number of morphemes, and can translate to entire phrases or clauses in English (Mallon, 2000; Micher, 2017; Joanis et al., 2020).[4]

Moreover, these morphemes are not easily segmented from one another, as they exhibit phonological changes at morpheme boundaries. That is to say, a given morpheme may be spelled in a number of different ways (or may even appear to merge with a neighbouring morpheme) depending on the morphemes adjacent to it. This means that automatic segmentation approaches may not be optimal. Nevertheless we try using them, and see if we can mitigate some of those challenges via experiments on joint vs. disjoint vocabularies and inserting noise into the segmentation process.

English is written in the Roman script (ISO 15924: Latn), while the Inuktitut data used for this task is primarily written in syllabics (ISO 15924: Cans).[5] There is some Roman text in the Inuktitut side of the data and some syllabics text in the English side of the data, though the former is much more common than the latter.

2.2 Domains and Recency Effects

The Inuktitut–English training corpus released for WMT 2020 consists of parliamentary transcriptions and translations from the Legislative Assembly of Nunavut (Joanis et al., 2020), while the development and test sets are a mix of parliamentary text and news text, the latter drawn from Nunatsiaq News.[6] These two domains are quite different from one another, and in our initial baseline experiments (training only on parliamentary data), we observed very low BLEU scores when translating news data. As we wished to build a constrained system, our only source of Inuktitut news was the data in the development set. In order to retain the ability to use news data in the development and test sets, we utilized an approach of dividing the news development data into thirds, including a third in the training set, using a third as part of the validation set, and holding the remaining third out as test.

The Nunavut Hansard is known to exhibit recency effects, i.e., when testing on a recent subset of the corpus, training on a recent subset is better than training on an early subset (Joanis et al., 2020). Although we have not fully examined the reasons behind this, it could be due to topic shift, a shift in the named entities in the corpus, changes in transcription and translation practices, or any combination of these and more.

We consider tagging domain as one approach to this. Sennrich et al. (2016a) use side constraints (tags) in order to control English–German MT output formality. Yamagishi et al. (2016) add information about voice (e.g. active/passive) to Japanese–English translation via source-side tags. Johnson et al. (2017) also use tags at the start of source sentences, in their case to indicate what language the multilingual translation system should translate into.[7] One might consider domain to fall somewhere between these use cases; Kobus et al. (2017) use domain tags to influence translation in a multi-domain setting. Caswell et al. (2019) use tags to indicate when data has been backtranslated.

3 Data

While the parallel text size for this language pair is quite small compared to high-resource language pairs in the news translation task, Inuktitut is one of the few Indigenous languages in Canada (or possibly the only) for which there exists enough parallel text (with any other language) to train robust statistical or NMT systems outside of the strictly low-resource paradigm (Littell et al., 2018). Thus we expect that it should be helpful to incorporate available monolingual data.

We trained our baseline models using the full 1.3 million line Nunavut Hansard 3.0 (NH) parallel corpus. For IU-EN, we also used a random subselection of 1.3M sentences of English Europarl v10 (Koehn, 2005; Tiedemann, 2012) and 1.3M sentences of English 2019 News data[8] backtranslated into Inuktitut (Section 5.4). We did not use

[4] The Inuktut Tusaalanga website provides an overview of grammar: https://tusaalanga.ca/node/1099

[5] A number of different writing systems, including both syllabics and Roman orthography, are used to write Inuit languages. Inuit Tapiriit Kanatami (ITK) is in the process of creating a unified writing system (Inuit Tapiriit Kanatami, 2020).

[7] Wang et al. (2018) add a target-side tag.

[8] From the WMT 2020 task page: https://www.statmt.org/wmt20/translation-task.html

Wiki Titles or Common Crawl Inuktitut data.[9] We incorporated the news portion of the development data in training our models to alleviate the domain mismatch issue (Section 5.1).

4 Preprocessing and Postprocessing

We first applied an internal script to convert control characters to spaces as well as normalizing spaces and hyphens; this was effectively a no-op for the Nunavut Hansard parallel corpus, but removed some problematic characters in the monolingual training data. Parallel training corpora were then cleaned with the Moses `clean-corpus-n.perl` script (Koehn et al., 2007), using a sentence length ratio of 15:1 and minimum and maximum lengths of 1 and 200, respectively. For monolingual training data, the second cleaning step consisted of removing empty lines. For Inuktitut, we used the `normalize-iu-spelling.pl` script provided by the organizers.

We then performed punctuation normalization. This included specific `en` and `iu` normalization scripts, to more accurately capture and retain information about directional quotation marks, different types of dashes, and apostrophes, normalizing to the most common form. For Inuktitut, this included treating word-internal apostrophes as U+02BC MODIFIER LETTER APOSTROPHE.[10] Appendix C provides a detailed description. After this preliminary normalization, we applied the Moses `normalize-punctuation.perl` script, with the language set to `en` (or backing off to `en`, as there are currently no Inuktitut-specific rules implemented).

Having noted that some of the lines in the training data contained more than one sentence (which results in unintended tokenization behavior), we next performed sentence splitting using the Portage sentence splitter (Larkin et al., 2010) on each side of the training data before feeding it to the Moses tokenizer (using aggressive hyphen splitting). Sentences that had been split were then re-merged following tokenization.

We trained joint byte-pair encoding (BPE; Sennrich et al., 2016c) models on the full Nunavut Hansard parallel training data using `subword-nmt`, then extracted English and Inuktitut vocabularies separately.[11] Using a joint BPE model improves performance on Roman text in Inuktitut output (Section 5.2 and Appendix B).

As postprocessing, we de-BPE the data, run the Moses detokenizer, and then convert the placeholder tokens from our normalization scripts to their corresponding symbols (dashes, apostrophes, quotation marks, etc.).[12]

5 Experiments

All models were typical transformers (Vaswani et al., 2017) with 6 layers, 8 attention heads, network size of 512 units, and feedforward size of 2048 units, built using Sockeye (Hieber et al., 2018) version 1.18.115. We have changed the default gradient clipping type to absolute, used the whole validation set during validation, an initial learning rate of 0.0001, batches of ∼8192 tokens, and maximum sentence length of 200 tokens. We have optimized for BLEU. Custom checkpoint intervals have been used during training, with final systems using between 2 and 11 checkpoints per epoch, consistent within sets of experiments (e.g., vocabulary size sweeping). For finetuning, the checkpoint interval is set to 9, resulting in about 2 checkpoints per epoch for news and 13 for Hansard. For finetuning, we used an initial learning rate of 0.00015 (decreasing by a factor of 0.7 if there was no improvement after 8 checkpoints). Decoding was done with beam size 5.

In the following sections, we describe the experiments that led to our submitted systems. Our final systems were trained on a mix of news and Hansard data (Section 5.1), using joint BPE (Section 5.2), BPE-dropout (for EN-IU; Section 5.3), tagged backtranslation (for IU-EN; Section 5.4), finetuning (Section 5.5), ensembling, and the use of domain-specific models (Section 5.6).

[9] Appendix E provides additional detail about noise and other concerns with the Common Crawl data.

[10] The apostrophe sometimes represents a glottal stop, so when it appeared between syllabic characters, we treated it as a letter that should not be tokenized.

[11] When extracting the BPE vocabulary (which we then used consistently for all experiments) and when applying the BPE model, we used a glossary containing the special tokens produced in preprocessing, Moses special tokens, and special tags (Section 5.4), to ensure they would not be split.

[12] During the task test period, we noted that the test data contained spurious quotation marks, wrapping some entire sentences. After notifying the organizers and confirming that those were produced in error, we handled them as followed: removed the straight quotes that surrounded complete lines, preprocessed, translated, and postprocessed the text that had been contained inside of them, and then reapplied the quotes to the output. There is not an exact match between the source and target for these spurious quotes, so this approach is effective but *not* an oracle.

5.1 Training and Development Splits

In baseline experiments, training only on the Nunavut Hansard training data provided, we noted a major difference in BLEU scores between the Hansard and news portions of the development set. While BLEU scores should not be compared directly across different test sets, the magnitude of this difference (in the EN-IU direction, BLEU scores in the mid-20s on Hansard and in the mid-single digits on news) and the knowledge of differences between parliamentary speech and the news domain suggested that there was a real disparity, likely driven by train/test domain mismatch.

To test this we divided the news portion of the development set in half, maintaining the first half as development data, and adding the second half to the training corpus. Adding half the news nearly doubled the BLEU score on the held out half of the news data, if we duplicated it between 5 and 50 times (to account for how much more Hansard data was available).[13] Initial experiments on vocabulary types and sizes were performed in this setting (Section 5.2).

For the remainder of our experiments, we switched to a setting where we divided the news data into three approximately equally sized thirds; to maintain most documents separate across splits, we split the data into consecutive chunks. Most experiments were run with the first third added to training data, the second third as part of the development set alongside the Hansard development set, and the final third as a held-out test set. This permitted additional experiments on finetuning (Section 5.5) with a genuinely held-out test set.[14] For our final systems, we ensembled systems that had been trained on each of the thirds of the news development data.

5.2 BPE

Ding et al. (2019) highlight the importance of sweeping the number of subword merges (effectively, vocabulary size) parameter, particularly in lower-resource settings. We swept a range of disjoint BPE size pairs (see Appendix A for details of vocabulary size and sweep), and found that disjoint 1k vocabularies performed well for IU-EN, while the combination of disjoint 5k (EN) and 1k (IU) vocabularies performed well for EN-IU (on the basis of averaged Hansard development and news development BLEU score).

As noted in Section 2.1, the Inuktitut data is written in syllabics. However, it contains some text in Roman script, in particular, organization names and other proper nouns. Over 93% of the Roman tokens that appear in the Inuktitut development data also appear in the corresponding English sentence. The ideal behavior would be for a system to copy such text from source to target. When the BPE vocabulary model is learned jointly the system can learn a mapping between identical source and target tokens, and then learn to copy. When the vocabulary is disjoint, there may not be identical segmentations for the system to copy, posing more of a challenge. Appendix B provides details of our experiments on joint vocabulary for successfully producing Roman text in Inuktitut output.

Due to the similarity in BLEU scores, and for simplicity and consistency, the remainder of our experiments *in both directions* were performed with jointly learned (and separately extracted) BPE vocabularies. We experimented with joint BPE vocabulary sizes of 1k, 2k, 5k, 10k and 15k.

5.3 BPE-Dropout

Knowing that the morphology of Inuktitut may make BPE suboptimal, we chose to apply BPE-dropout (Provilkov et al., 2020) as implemented in `subword-nmt` in an attempt to improve performance. BPE-dropout takes an existing BPE model, and when determining the segmentation of each token in the data randomly drops some merges at each merge step. The result is that the same word may appear in the data with multiple different segmentations, hopefully resulting in more robust subword representations. Rather than modifying the NMT system itself to reapply BPE-dropout during training, we treated BPE-dropout as a preprocessing step. We ran BPE-dropout with a rate of 0.1 over both the source and target training data 5 times using the same BPE merge operations, vocabularies and glossaries as before, concatenating these to form a new extended training set.[15]

In our initial baseline experiments (without

[13] Adding all of the data would not have allowed us to evaluate the outcome on news data, and not including any news data in the development set also hurt performance.

[14] An alternative approach would be to select pseudo in-domain data from the Hansard, by finding the Hansard data that is most similar to the news data (Axelrod et al., 2011; van der Wees et al., 2017). While this may be worth exploring, we felt the extreme discrepencies between news and Hansard merited examination with gold in-domain data.

[15] We also experimented with 11 and 21 duplicates of the training data, and dropout rates of 0.2; we did not observe major differences between the settings.

news data in training), we found that BPE-dropout was more helpful in the IU-EN direction (+∼0.4 BLEU) than in the reverse (+∼0.2 BLEU). After incorporating a third of the news data in training, we found the reverse: a small increase for IU-EN (+∼0.1) and a slightly larger increase for EN-IU (+∼0.3).

5.4 Tagging and Backtranslation

By incorporating news data into our training set (Section 5.1), we improve performance on news data. However, the approach is sensitive to the number of copies of news data added, which can decrease performance on both Hansard and news data if not carefully managed. Both English news data and monolingual English parliamentary data (from Europarl) are plentiful in WMT datasets, so we incorporated them into our models via backtranslation (Sennrich et al., 2016b).

We apply approaches from Kobus et al. (2017) and Caswell et al. (2019): tagging source data domain (<NH> or <NEWS>) and (for IU-EN) tagging backtranslated source data (<BT>). Tagging domain appears to be particularly important for translating into Inuktitut, with between 1.4 and 2.4 BLEU points improvement on a subset of the news development test and minimal effect on the Hansard development data scores.

For backtranslation, we chose random samples of Europarl and WMT 2019 news data, experimenting with 325k, 650k, and 1.3M lines each, with 1.3 million performing best.[16] Ablation experiments with just news or just Europarl data showed less promise than the two combined. We did not perform backtranslation of Inuktitut (see Appendix E).

We performed two rounds of backtranslating the randomly sampled 1.3M lines each of Europarl and WMT 2019 news data. The first round (BT1) used our strongest single 5k joint BPE (with dropout) EN-IU system at the time. The second round (BT2) used a stronger three-way ensemble, with improved performance on both Hansard and news.

We experimented with combinations of tags for the backtranslated data (other parallel corpora have source domain tags unless otherwise stated):

- tagging all backtranslated data with <BT>;
- tagging backtranslated data with both <BT> and domain tags, where the domain tag matches the closest parallel corpus domain, i.e., <BT> <NH> or <BT> <NEWS>.[17]
- tagging backtranslated data with just a domain tag matching the closest parallel corpus domain, i.e. <NH> or <NEWS>.
- tagging all backtranslated data with <BT>, but not domain tagging the parallel corpora.
- tagging nothing.

As Table 1 shows for IU-EN translation, using backtranslated Europarl and news text clearly helped translating news text (as much as 8.0 BLEU) while only slightly impacting the translation of Hansard text. Without any backtranslated text, using domain tags (<NH> for Hansard and <NEWS>) appears to have a small positive effect on Hansard translation, and none on news (contrary to what we observed in the EN-IU direction).

The main observation from these experiments was that it was most important to distinguish backtranslation from true bitext (an observation similar to those noted in Marie et al. (2020)). Our best results were observed with no tags for the bitext and the <BT> tag for the backtranslated data. These experiments finished after the deadline, so our final submission uses the the next best combination: domain tags for bitext and <BT> tags for backtranslation.[18]

5.5 Finetuning

After building models with domain tags and backtranslation (in the case of IU-EN), we turned to finetuning to see if there was room to improve.

For systems that had been trained on Hansard data concatenated with the first third of the news development data, we experimented with finetuning on just that same first third of news data (using the second third for early stopping and the final third for evaluation), as well as both the first and second thirds (using the final third for both early stopping and evaluation). These approaches improved translation performance in terms of BLEU on the remaining third, with the use of more news data being more effective.[19]

[16] This was the largest size tested; it remains possible that increasing it even more could lead to even better performance.

[17] We also experimented with using novel tags for the domains of the backtranslated data (<PARL> and <EN-NEWS>) with and without additional <BT> tags, but found this had approximately the same effect as combining the backtranslation and domain tags, so we omit it from Table 1.

[18] Additional details of the backtranslation systems and these experiments are in Appendix D.

[19] We expect that training on more of the news data from the start (i.e., two thirds) might improve performance even more, but for our initial experiments we chose to use one third in

Backtranslation Data	Bitext Source Tag	Backtranslation Tag	NH	News.03	Avg
—	—	—	41.0	18.0	29.5
—	<NH|NEWS>	—	**41.3**	18.0	29.7
BT1	—	—	41.0	22.9	32.0
BT1	<NH|NEWS>	<NH|NEWS>	41.0	21.6	31.3
BT1	<NH|NEWS>	<BT> <NH|NEWS>	40.9	23.5	32.2
BT1	<NH|NEWS>	<BT>	40.7	23.8	*32.3*
BT2	—	—	40.8	23.6	32.2
[FINAL] BT2	<NH|NEWS>	<BT>	41.0	25.1	33.1
BT2	—	<BT>	40.9	**26.3**	**33.6**

Table 1: Backtranslation tag experiments on: IU-EN 15k Joint BPE, NH + News.01 (duplicated 15 times), 1.3M EuroParl, 1.3M News. Cased word BLEU scores measured on Hansard (NH) and last third of news (News.03; final 718 lines) portions of newsdev2020-iuen.

We also found that we were able to improve translation of Hansard data by finetuning on recent data. Joanis et al. (2020) observed recency effects when building models with subsets of the data. Here we take that observation a step further and find that finetuning with recent data (Hansard training data from 2017, which was already observed in training) produces BLEU score improvements on Hansard development data on the order of 0.5 BLEU into English, and on the order of 0.7 BLEU into Inuktitut (Tables 2 and 3).[20]

Despite the use of domain tags, finetuning on one domain has negative results for the other (see Tables 2 and 3).

5.6 Ensembling and Hybrid Model

Our hope was to build a single system to translate both news and Hansard but, in the end, we found that our attempts at finetuning for the combination of news and Hansard were outperformed by systems finetuned to one specific domain. Maintaining a held-out third of news data allowed us to measure performance of ensembled models on news data, so long as we only ensembled systems that had not trained on that held-out data. In order to create our final submissions, we chose finetuned systems based on the held-out third, and then ensembled them with the assumption that the strong ensemble with access to the full news development data would outperform the individual systems or pairs of systems trained on subsets. In general, we found that ensembling several systems (using Sockeye's built-in ensembling settings) improved performance. However, this had some limits: for EN-IU if we combined a strong news system whose performance on Hansard had degraded too much with a strong Hansard system whose performance on news had degraded, the final result would be poor performance on both domains.

Our solution to this was simple: decode news data with an ensemble of models finetuned on news, and decode Hansard data with an ensemble of models finetuned on Hansard. Our final submissions are hybrids of domain-specific systems.[21]

System	NH Dev.	ND 3	NH Test	News Test	Full Test
Base: NH+ND.1	24.7	11.7	16.7	11.6	14.1
Base: NH+ND.2	24.7	11.3	16.7	11.2	13.9

6 Submitted Systems

6.1 English–Inuktitut

Our primary submission for EN-IU is a hybrid of two joint BPE 10k ensembled systems with

order to enable us to measure improvements on a held-out set; see Section 5.6 for our efforts to use ensembling to balance the usefulness of training on more data with the ability to measure progress during preliminary experiments.

[20] Note that there is a fine distinction between the two settings here: when finetuning on recent Hansard data, the system is training on data it has already seen. When finetuning on news data, we expose the system to some data it has already seen (one third of the news data) and some data that it has *not* trained on (another third of the news data).

[21] This leaves questions open, e.g., if a Hansard system trained without any news data would perform as well or better on Hansard test data than one trained with news data.

System	NH Dev.	ND 3	NH Test	News Test	Full Test
BT1:NH+ND.1	40.7	23.8	29.0	21.6	25.6
BT2:NH+ND.1	41.0	25.1	29.3	22.1	25.9
BT2:NH+ND.2	41.1	25.1	28.9	22.9	26.1
BT2:NH+ND.3	41.1	–	28.7	22.6	25.9
Ensemble	41.7	–	29.6	24.8	27.4
F.t. ND.{1,2}	39.9	**26.7**	28.5	23.9	26.4
F.t. ND.{2,3}	39.6	–	28.2	23.8	26.1
F.t. ND.{3,1}	40.1	–	28.4	23.7	26.2
Ens.: F.t. ND	40.9	–	29.1	**25.8**	27.6
F.t. NH (from 1)	41.6	23.6	29.0	21.0	25.3
F.t. NH (from 2)	41.5	24.6	28.9	22.8	26.1
F.t. NH (from 3)	41.5	–	28.8	21.6	25.5
Ens.: F.t. NH	**42.4**	–	**29.9**	24.3	27.3
Final hybrid	**42.4**	–	**29.9**	**25.8**	**28.0**

domain tags. To translate the Nunavut Hansard data, we used an ensemble of three systems, all finetuned on 2017 Hansard data using only the Hansard development data for validation during finetuning. The three base systems used for finetuning were trained on the full Hansard along with the first, second, or third news third (duplicated 15 times), respectively, with BPE-dropout on both the source and target sides.

To translate the news data, we again used an ensemble of three base systems trained with BPE-dropout on both the source and target sides: a base system trained on all Hansard data with the first third of news data (duplicated 15 times) finetuned on the first and second third of news data, another such base system trained instead with the second third of news data (duplicated 15 times) and finetuned on the second and third third of news data, and a final base system trained with the third third of news data (duplicated 15 times) and finetuned on the first and third thirds. The hybrid system had a BLEU score of 15.8 on the test data (Table 2).

6.2 Inuktitut–English

Our primary submission for IU-EN is a hybrid of two joint BPE 15k ensembled systems with domain tags (for news and Hansard bitext) and backtranslation tags (for the backtranslated data). Due to time constraints, we did not run BPE-dropout. Like the EN-IU direction, we built three baseline systems. All baseline systems were trained on the full Hansard training data, along with 1.3 million lines of backtranslated Europarl data and 1.3 million lines of backtranslated news 2019 data. The three baseline systems differed in which third of news was used for training, as described for EN-IU. Backtranslation was performed using an ensemble of the three baseline systems used for the EN-IU task (joint BPE 10k, BPE-dropout).

We performed finetuning on news and recent Hansard in the same manner as for EN-IU. The news test data was translated with the ensemble of news-finetuned systems, while the Hansard test data was translated with the ensemble of the Hansard-finetuned systems. The final system had a BLEU score of 28.0 on the test data (Table 3).

7 Conclusions and Future Work

We have presented the results of our IU-EN and EN-IU systems, showing that a combination of BPE-dropout (for EN-IU), backtranslation (for IU-EN), domain-specific finetuning, ensembling, and hybrid systems produced competitive results. We performed automatic evaluations of the submitted systems in terms of BLEU, chrF (Popović, 2015), and YiSi-1 (Lo, 2020). Our EN-IU system performed best out of the constrained systems in terms of BLEU (15.8, +2.5 above the next-best system), chrF (37.9, +1.7 above the next-best), and YiSi (82.4, +0.5 above the next-best). Our IU-EN system performed third-best out of all systems in terms of BLEU (28.0, -1.9 below the best system), third-best in terms of chrF (48.9, -2.0 below the best system), and third-best in terms of YiSi-1 (92.3, -0.6 behind the best system).[22]

There remains a wide range of future work to be done to improve translation for this language pair. There is still space to improve Roman text output in Inuktitut, perhaps even as simply as an automatic postediting approach. Different subword segmentations (or ones complementary to BPE-dropout like He et al. (2020)), particularly ones that capture morphological and phonological aspects of Inuktitut may also be promising.

In terms of adding monolingual data, we expect that improved data selection for backtranslated data (i.e., to increase topic relevance) may be useful, as would additional Inuktitut monolingual data. Due to time constraints, we were unable to complete BPE-dropout for IU-EN systems; we expect this would have resulted in improved performance.

[22] We do not have information about whether any of these systems were unconstrained. It is also worth noting that the highest-ranked systems differed depending on the metric used, so we await human evaluation.

Domain finetuning remains a challenge given the very small amount of parallel news data available. We did experiment with mixing Hansard and news data for finetuning, but, contrary to Chu et al. (2017), were unable to outperform news-only systems on news. It may be worth trying approaches designed to prevent catastrophic forgetting in domain adaptation (Thompson et al., 2019).

The real test, of course, will be human evaluation; are the systems producing output that might be usable, whether for computer aided translation (via postediting or interactive translation prediction) or for use in other downstream applications?

Acknowledgments

We thank the reviewers for their comments and suggestions. We thank Eddie Santos, Gabriel Bernier-Colborne, Eric Joanis, Delaney Lothian, and Caroline Running Wolf for their comments and feedback on the paper. We thank Chi-kiu Lo for providing automatic evaluation scores of submitted systems. We thank the language experts at Pirurvik Centre for their work on the forthcoming human annotations, and the Government of Nunavut and Nunatsiaq News for providing and allowing the use and processing of their data in this shared task.

A Data and BPE Sizes

For reproducibility, we show the data sizes after cleaning in Table 4. Exact sizes for BPE vocabularies (including codes, and extracted vocabulary sizes) are shown in Table 5.

For IU-EN, we tried disjoint (Inuktitut, English) models with BPE size pairs: (500,500), **(1k,1k)**, (5k,5k), (10k,10k), (500,5k), (1k,5k), and (5k,10k). For EN-IU, we tried disjoint (English, Inuktitut) models with BPE size pairs: (500,500), (1k,1k), (5k,5k), (10k,10k), **(5k,1k)**, (10k,1k), (10k,5k). The typological differences between English and Inuktitut motivated these experiments on vocabulary sizes, testing whether unbalanced sizes may be better than balanced sizes when using disjoint vocabularies. Our intuition was that smaller vocabulary sizes for Inuktitut and larger vocabulary sizes for English might lead to mappings between vocabulary items that were closer to one-to-one.

We also tried using SentencePiece Unigram models (Kudo, 2018) trained for the same size pairs, but they did not yield improvements in BLEU score, so we used `subword-nmt` for the remainder of our experiments.

B Roman Text in Inuktitut Output

When Roman text appears in the Inuktitut side of the Hansard, that same text almost always appears in the English side of the data. In the test data, this is the case for all but 9 of the 151 Roman tokens on the Inuktitut side of the data (over 94%).[23] Thus we expect a good NMT system should learn to produce Roman output that matches some portion of the Roman text in the English input (or at least, that should be true for *most* Roman text it produces).

When the BPE vocabulary model is learned jointly, this task has the potential to be trivial: the system simply needs to learn which source vocabulary tokens are the same as which target vocabulary tokens and then copy them, and RNN-based NMT systems are known to be able to use context in order to do this (Knowles and Koehn, 2018). When the BPE vocabularies are learned independently, however, such words may be broken into different sequences of subwords on the source and target sides, a more challenging task for the system to handle. Intuitively, the system must learn to spell to do this successfully. This led us to experiment with joint vocabulary models. We measured precision, recall, and F1 averaged across Hansard and news development data for Roman words (whole words, after de-BPE, but prior to detokenization) for systems trained using disjoint vocabulary models and those with vocabularies trained jointly (but extracted separately). We found comparable BLEU scores between the two settings, but found that average F1 was higher in the joint setting.

In Table 6, we see three systems from an early set of experiments with identical BLEU scores (the best out of their respective vocabulary size and data balancing sweeps; the disjoint system had the news data repeated 30 times, while the 2k joint system had it repeated 10 times and the 10k joint system had it repeated 30 times). The joint systems had higher F1 scores, particularly driven by improvements in precision (on Hansard, an increase from 30.9% precision to 38.7% and 35.7% and on news an increase from 28.1% to 49.2% and 43.2%).

Nevertheless, as evidenced by the relatively low F1 scores, there best systems still make some errors, as shown in the example below:

Src: Mr. Speaker, the Indspire Awards represent the highest honour the indigenous community presents to its people.

Ref: ᐅᖅᑲᖅᑎ, ᑕᒃᑯᐊ ᐱᑕᖓᖅᑕᖅᑐᑦ ᑭᓪᓗᖅᑐᐃᓂᖅ >ᖅᑐᓂᖅᐸᒥᒃ, ᐅᐱᐟᓇᖅᑐᒥᐅᑕᑯᓗᐃᑦ ᑕᕐᕋᖏᓪ ᓄᓇᖅᑲᖅᓱᖅᑐᙵᔪᓂᖅᓄᑦ ᐃᓄᖅᑯᑎᖏᓐᓄᑦ.

MT: ᐅᖅᑲᖅᑎ, ᑕᒃᑯᐊ Inspiration Award-ᖏᔪᓂᖅᑕᐅᕐᒃ ᖅᑯᑦᑎᓂᖅᐸᒥᒃ ᓄᓇᖅᑲᖅᓱᖅᑐᒥᓂᖅᓄᑦ ᐃᓄᖅᑯᑎᒥᓄᑦ. ᑐᓂᓯᖅᑕᑦᒪᑕ

There are in fact two errors in this MT output: first, the system generates Roman text that it perhaps ought not to have generated, and second it does not successfully copy *Indspire*, instead producing *Inspiration*. This suggests that, although using joint BPE has improved Roman text output in Inuktitut, there is still room for additional improvement. Our final submission had an F1 score of 27.4 (41.3% precision and 20.5% recall)

[23] Of the 9 exceptions, 6 were cases where one side used an abbreviation and the other expanded it, 1 was a plural/singular distinction, 1 was a capitalization difference, and 1 was a spelling difference.

Joint BPE 2k	24.7	25.9
Joint BPE 10k	24.7	27.6

Table 6: Comparison of best disjoint and joint BPE systems trained using Nunavut Hansard and half of the news data as training, scored with BLEU and with Roman text F1 averaged over the Hansard development data and the other half of the news development data. These were early systems trained without tags or back-translation.

C Preprocessing and Postprocessing

In this appendix, we provide detail about our additional language-specific preprocessing and postprocessing.

C.1 Preprocessing

Our additional preprocessing focuses on quotation marks, apostrophes, and some other punctuation. We first describe English-specific preprocessing.

We normalize double quotation marks to three distinct special tokens, `-LDQ-`, `-RDQ-`, and `-UDQ-` (left, right, and unknown double quote, respectively), separated from any surrounding characters by a space. For directional quotation marks ('LEFT DOUBLE QUOTATION MARK' (U+201C) and 'RIGHT DOUBLE QUOTATION MARK' (U+201D)), this is a simple substitution. For straight quotations ('QUOTATION MARK' (U+0022)), we apply the following heuristics: those followed by a space are right, those preceded by a space are left, those followed by punctuation (period, comma, question mark, semicolon) are right, those at the beginning of a line are left, those at the end of a line are right. All that remain are considered unknown.

For single quotes or apostrophes ('LEFT SINGLE QUOTATION MARK' (U+2018) and 'RIGHT SINGLE QUOTATION MARK' (U+2019)), we do as follows. We first convert any instances of 'GRAVE ACCENT' (U+0060) to the right single quote (this is rare but manual examination of the training data suggests that they are used as apostrophes). We then convert any instances of left and right single quotation marks to special (space-separated) tokens `-LSA-` and `-RSA-`, respectively. We next consider 'APOSTROPHE' (U+0027). That token followed by a space is mapped to `-RSA-`, while any instances preceded by a space are mapped to `-LSA-`. Any that are sandwiched between alphanumeric characters (a-z, A-Z, 0-9) are treated as a word internal apostrophe, `-RSI-`. Remaining ones preceded by alphanumeric characters are mapped to `-RSA-`, while those followed by alphanumeric characters are mapped to `-LSA-`. Any remaining at this point are mapped to `-ASO-` (other).

We also map 'EN DASH' (U+2013) to -NDA- and 'EM DASH' (U+2014) to -MDA- (as ever, keeping these special tokens space-separated from remaining text).

For Inuktitut, we use similar substitutions, noting the differences below. This is run after the spelling normalization script provided. For quotation marks, any instances of 'LEFT SINGLE QUOTATION MARK' (U+2018) followed immediately by 'RIGHT SINGLE QUOTATION MARK' (U+2019) are treated as -LDQ-, while any instances of two 'RIGHT SINGLE QUOTATION MARK' (U+2019) in a row are treated as -RDQ-. Double apostrophe is first mapped to 'QUOTATION MARK' (U+0022). Those straight double quotes preceded *or* followed by punctuation (period, comma, question mark, semicolon) are treated as -RDQ-. We expand the earlier alphanumeric matching to include the unicode character range 1400-167F, which contains all syllabics present in the data.

There are five observed types of single quotes or apostrophes in the data. The most common is 'RIGHT SINGLE QUOTATION MARK' (U+2019), appearing more than 9000 times, followed by 'APOSTROPHE' (U+0027), appearing more than 1300 times, followed by 'GRAVE ACCENT' (U+0060), over 600 times, 'LEFT SINGLE QUOTATION MARK' (U+2018), which appears fewer than 200 times, and 'ACUTE ACCENT' (U+00B4), which appears very rarely. We first map the grave accent to 'RIGHT SINGLE QUOTATION MARK' (U+2019). Then, for the remaining four types, if they appear within syllabics (range U+1400 to U+167F), we map them to 'MODIFIER LETTER APOSTROPHE' (U+02BC). This is important because this is then treated as a *non-breaking* character for the purposes of Moses tokenization. It often represents a glottal stop, which *should* be treated as part of the word, not necessarily as something to split on. When one of the four types appears at the end of a word, it is treated as a -RSA- if a left single apostrophe was observed before it in the sentence. Any remaining at the ends of syllabic words are treated as modifier letter apostrophe. Any of the four that appear between non-syllabic alphanumeric characters are mapped to -RSI-. Remaining left single quotation marks are mapped to -LSA-, while remaining right single quotations and acute accents are mapped to -RSA-. Apostrophes are then mapped in the same manner as English, with the addition of the syllabic range to the alphanumeric range.

C.2 Postprocessing

The postprocessing is done to revert the placeholder tokens to appropriate characters and is done after de-BPE-ing and Moses detokenization.

For English, we do as follows. The placeholder -LDQ- and any spaces to the right of it are replaced with 'LEFT DOUBLE QUOTATION MARK' (U+201C), while -RDQ- and any spaces to the left of it are replaced with 'RIGHT DOUBLE QUOTATION MARK' (U+201D), and -UDQ- is replaced with 'QUOTATION MARK' (U+0022) with no modification to spaces.

The -RSI- token and any surrounding spaces are replaced with 'RIGHT SINGLE QUOTATION MARK' (U+2019), -RSA- and any spaces preceding it are replaced with 'RIGHT SINGLE QUOTATION MARK' (U+2019), -LSA- and any spaces following it are replaced with 'LEFT SINGLE QUOTATION MARK' (U+2018), and -ASO- is replaced with 'APOSTROPHE' (U+0027).

The em-dash placeholder is replaced with an em-dash without surrounding spaces, while the en-dash placeholder is replaced with an en-dash *with* surrounding spaces. We also perform some other small modifications to match the most common forms in the original text: spaces around dashes and forward slashes are removed, times are reformatted (spaces removed between numbers with colons and other numbers), space between greater than signs is removed, space is removed before asterisks, spaces are removed following a closing parenthesis that follows a number, three periods in a row are replaced with 'HORIZONTAL ELLIPSIS' (U+2026), space is removed after asterisk that begins a line, space is removed after the pound sign, and space is removed between a right apostrophe and a lowercase s.

For Inuktitut, the postprocessing is similar, with the following changes/additions: the modifier letter apostrophe is replaced with the 'RIGHT SINGLE QUOTATION MARK' (U+2019), no spaces are placed around the en-dash, and spaces are removed between a close parenthesis followed by an open parenthesis.

D Backtranslation Details

Here we describe details of our backtranslation experiments. The first pass (BT1) employed our strongest English–Inuktitut system at the time, trained on the Nunavut Hansard bitext plus the first third of the news bitext (from newsdev2020-eniu) using 5k joint BPE with BPE-dropout on both source and target. Later, we backtranslated the data a second time (BT2) using a stronger three-way ensemble of systems, each of which was trained on the NH corpus and a different third of the news bitext from newsdev2020-eniu using 10k joint BPE with BPE-dropout on both source and target. This ensemble improved the BLEU score on the NH portion of newsdev2020-eniu by 0.5 BLEU (from 24.5 to 25.0); while we could not measure the improvement of the 3-way ensemble on news data, an ensemble of two of these systems (trained using one of the first two thirds of news) yielded a 1.5 boost in BLEU measured on the final news third (from 12.1 to 13.6) over the system used for the first round. Thus the ensembled system used for this second round of backtranslation was stronger at translating both parliamentary and news data.

With BT1 backtranslated data, positive effects came from ensuring that backtranslated data and true bitext are tagged differently. Tagging the backtranslated source with the exact same domain tags as the parallel data leads to a decrease in performance of 1.7–2.2 BLEU for translating news; it is even worse (by 1.3 BLEU on news) than using no tags at all.

While most round one (BT1) backtranslation tagging methods yielded news data BLEU increases between 0.4 and 0.8 (over not tagging), a larger improvement of $\geq$1.5 BLEU occurred when using our second round of backtranslated data (BT2); notably, the worst system trained using BT2 scores only 0.1 BLEU (average) below the best BT1 system. Our best performance was achieved using BT2 backtranslations with <BT> tags but no domain tagging (for either the parallel or backtranslated source). It outperformed the next best system by 1.2 BLEU on news; unfortunately those experiments did not complete before the deadline. Thus our submitted system used the best available systems at the time for additional finetuning: domain tags on parallel data and <BT> tags on the backtranslated data.

Each of the individual systems that contributed to our final Inuktitut–English system combination used 1.3 million lines of Europarl (tagged as <BT>), 1.3 million lines of news (tagged as <BT>), approximately 1.3 million lines of Nunavut Hansard (tagged as <NH>), and 719 or 718 lines of news (tagged as <NEWS> and duplicated 15 times).

E Inuktitut Common Crawl and Additional Data

We did not use any data from Inuktitut Common Crawl in our submissions. In our initial experiments, we found it generally harmed translation quality. Nevertheless, we provide here some observations from our analysis, in the hopes that they are useful to other researchers. First, the Common Crawl data provided contains fairly large amounts of non-Inuktitut data. This includes noise, such as long sequences of characters (like lists of characters) as well as text art (such as English words spelled using visually similar syllabics and other characters, e.g., ᕼᕮᒪᒪᑐ). There is also text in several other languages and dialects, including, but likely not limited to: ᓇᓴᐲᐱᐣ (Naskapi),[24] ᓂᐦᐃᔨᐁᐧᐃᐦᐣ (Plains Cree), and ᓄᓇᕗᑦᑎᐅᑎᑐᑦ (Nunavimmiutitut, an Inuit language spoken in Nunavik).[25] Of particular note is the latter, which – while it is the only one of the three within the Inuit dialect continuum that includes Inuktitut – is an Inuit language (sometimes called the Nunavik dialect of Inuktitut) that makes use of one additional column in the syllabary (∇, ∨, ∪, ..., or *ai*, *pai*, *tai*, ...). Those characters do not appear in the Hansard, thus rendering it impossible for our systems to translate them exactly without some form of modification, even if they might otherwise share similarities with words that appear in the Hansard. Removing characters that were not observed in the Hansard data (which helps filter out some non-Inuktitut language data) and filtering out potential text art results in a much smaller Common Crawl data set, less than half the size of the original.

While additional monolingual or bilingual data would likely benefit English to Inuktitut translation, we encourage non-Inuit researchers who plan to perform data collection to do so in collaboration with Inuit communities and language speakers.

[24] Text appears to be scraped from the Naskapi Community Web Site, http://www.naskapi.ca/.

[25] https://www.kativik.qc.ca/our-schools/resources/

The efforts of Inuit language experts at Pirurvik Centre were vital to the analysis of the data used for this task (Joanis et al., 2020), collected through communications with Nunatsiaq News and the Government of Nunavut with the goal of selecting data usable for this translation task, both in terms of public availability and language. Aside from the machine learning related risks of accidentally collecting data from other languages and labeling it as Inuktitut (as we observed in the Common Crawl data), there are also ethical concerns. While it does not focus specifically on language data, the National Inuit Strategy on Research (NISR, Inuit Tapiriit Kanatami, 2018) highlights as a priority "Ensuring Inuit access, ownership and control over data and information" and focuses on partnership with Inuit organizations, transparency, and data sharing to end exploitative research practices and build research relationships that respect Inuit self-determination.[26] The NISR contains a discussion of potential harms of research done without relationships to the communities impacted by it, with both Inuit-specific concerns and concerns from a broader history of colonialism. Lewis et al. (2020) provide a discussion of guidelines for Indigenous-centred AI from a variety of Indigenous perspectives (though not specifically from Inuit perspectives), including topics of ethics, data sovereignty, and responsibility and relationships in AI. Building and maintaining community relationships and collaborations can help ensure that data is handled and shared in ways that respect cultural values and Indigenous intellectual property,[27] which outsiders may not be familiar with. A full discussion of these topics is beyond the scope of this paper, but we raise the discussion here as part of the process of working towards best practices in building respectful research relationships that centre community goals at all steps of the research process.

F Statement on Avoiding Conflicts of Interest

In their work on ethical considerations in shared tasks, Parra Escartín et al. (2017) raise the issue of actual or perceived conflicts of interest between task organizers and participants. We provide the following information in the interest of transparency.

The data for the shared task on Inuktitut-English was collected by researchers at the National Research Council of Canada (NRC) in collaboration with the Pirurvik Centre.[28] The team of researchers at NRC was divided into two groups: those working on task organization and those participating in the shared task (the latter group are the authors of this paper). In order to prevent unfair advantages to the task participants, the organizers did not discuss the web source or details of the evaluation set with the participants at any time before the submission of the systems.

We did communicate with the organizers to receive clarification regarding the spurious quotes in the test data; the response to this was distributed to the full WMT mailing list.

CUNI Submission for the Inuktitut Language in WMT News 2020

Tom Kocmi

Charles University, Faculty of Mathematics and Physics
Institute of Formal and Applied Linguistics
Malostranské náměstí 25, 118 00 Prague, Czech Republic
kocmi@ufal.mff.cuni.cz

Abstract

This paper describes CUNI submission to the WMT 2020 News Translation Shared Task for the low-resource scenario Inuktitut–English in both translation directions. Our system combines transfer learning from a Czech–English high-resource language pair and backtranslation. We notice surprising behaviour when using synthetic data, which can be possibly attributed to a narrow domain of training and test data. We are using the Transformer model in a constrained submission.

1 Introduction

The rapid development of Neural Machine Translations (NMT) systems helped NMT in approaching human translation quality for high-resource language pairs like Chinese–English (Hassan et al., 2018) or English–Czech (Popel et al., 2020). This is not true for a low-resource scenario, where the lack of a large quantity of parallel data limits the performance of an NMT system. Thus, in recent years the research focused on low-resource NMT become important.

In this paper, we describe our approach to low-resource NMT of Inuktitut–English. We use the standard Transformer-big model (Vaswani et al., 2017) and apply two techniques to improve the performance on the low-resource language, namely transfer learning (Kocmi and Bojar, 2018) and backtranslation (Sennrich et al., 2016). We used a similar approach in WMT19 for Gujarati and Kazakh machine translation (Kocmi and Bojar, 2019).

Training low-resource model solely on authentic parallel data results in poor performance, and that results in low quality of generated backtranslation of monolingual data as well. Hence transfer learning is as an excellent method to first improve the performance of the NMT system that is later used for backtranslation of monolingual data.

2 Background

In this section, we describe the technique of transfer learning, backtranslation, and models that we used for training Inuktitut–English models.

2.1 Transfer Learning

Kocmi and Bojar (2018) presented a method of transfer learning that uses a high-resource language pair to train the "parent" model. After the training convergence, the parent training data are replaced with the training data of the low-resource language pair ("child"). Then the technique of fine-tuning continues without changing any parameters, resetting moments, nor changing the learning rate.

This technique has one shortcoming, and that is the problem with vocabulary mismatch. Kocmi and Bojar (2018) overcome this problem by preparing a shared vocabulary for all languages in both parent and child language pairs in advance. Their approach is to prepare a mixed subword vocabulary from the concatenation of training corpora for both languages.

We use their *balanced vocabulary* approach that combines an equal amount of parallel data from both training corpora, under-sampling the high-resource language pair as needed. Hence the low-resource language subwords are represented in the vocabulary with roughly the same prominence as the high-resource language pair ones.

Kocmi (2019) showed that parent and child language pairs do not have to be linguistically related, and more crucial criterion is the amount of parent parallel data. For this reason, we have selected Czech–English as a parent language pair, because it is one of the most resource-full languages allowed for WMT 2020.

Proceedings of the 5th Conference on Machine Translation (WMT), pages 171–174
Online, November 19–20, 2020.

2.2 Backtranslation

The amount of available monolingual data typically exceeds the amount of available parallel data. One of the techniques for using monolingual data in NMT is called backtranslation (Sennrich et al., 2016). It uses a model trained in the reverse direction to translate monolingual data to the source language of the first model. Backtranslated sentences are then aligned with their monolingual sentences to create synthetic parallel corpora. The standard practice is to mix the authentic parallel corpora with the synthetic ones, although it is not the only possible approach. Popel (2018) obtained better results by repeatedly alternating between the training on the authentic and the synthetic portion of the parallel data instead of mixing them. We got inspired with this approach, and after training on synthetic data, we add a step to fine-tune again with authentic parallel data.

The performance of the backtranslation model is essential. Especially in the low-resource scenario, where the baseline models trained only on the authentic parallel data have a poor score, and they generate very low quality backtranslated data. Therefore, we first improve the performance of baseline with the transfer learning and generate the synthetic data of better quality.

Synthetic data can be noisy; therefore, we remove synthetic sentence pairs containing repetitive patterns, which is often a case of bad translation. We also remove sentences that contain Latin script in Inuktitut translations as Inuktitut has its script. This filtration reduced the number of synthetic sentences from 51.7M to 45.5M sentences.

2.3 Datasets and Model

All our models are trained only on the data allowed for the WMT 2020 News shared task. We use all available parallel data for Inuktitut–English prepared by Joanis et al. (2020). We use Czech–English corpus CzEng20 created by Kocmi et al. (2020) as a parent language pair. This corpus contains 61M authentic parallel sentences and also two sets of synthetic parallel sentences of similar size. For training parent model, we used all authentic parallel data plus one set of synthetic data with authentic English part. We ignored synthetic data with authentic Czech. The reason is that we assume the child model transfers knowledge mainly for the English language that is shared between both parent and child language pair. Additionally, we use monolingual English sentences from News Crawl 2018 and 2019 for backtranslation step. Results in section 3 are computed based on official WMT20 testset for Inuktitut–English (Joanis et al., 2020). All used training data are presented in table 1. We remove empty lines from Inuktitut–English training set.

Lang. pair	Sent. pairs	Words (CS/IU)	Words (EN)
CS–EN	137.2M	1913M	2176M
IU–EN	1.3M	8M	17M
Mono EN	51.7M	-	1756M

Table 1: More details on the training sizes of training corpora. Columns with words show number of words separated by space. All data are from http://statmt.org/wmt20/.

As for the model, we use the Transformer "big single GPU" configuration as described in Vaswani et al. (2017), model which translates through an encoder-decoder with each layer involving an attention network followed by a feed-forward network. We use the version 1.11 of sequence-to-sequence implementation of Transformer called tensor2tensor.[1]

Popel and Bojar (2018) documented best practices to improve the performance of the model. Based on their observation, we use the Adafactor optimizer with inverse square root decay and 16000 warmup steps. Based on our previous experiments (Kocmi et al., 2018), we set the maximum number of subwords in a sentence to 100. The benefit is that the batch size can be increased to 4500 for our GPUs. The experiments are trained on a single GPU NVidia GeForce 1080 Ti or Quadro P5000.

3 Results

All reported results are calculated on the testset of WMT 2020 and evaluated with case sensitive SacreBLEU (Post, 2018).[2] The evaluation is done on unmodified outputs of our system. For final WMT20 submission, we have automatically corrected quotes to match the source. This step is not used for results in table 2.

The baseline models in table 2 are trained on the authentic data only. We have not focused on the backtranslation step for EN→IU as there are only 165k monolingual Inuktitut sentences available.

In IU→EN "Transfer from CS–EN" we get an

[2] The SacreBLEU signature is BLEU + case.mixed + numrefs.1 + smooth.exp + tok.13a + version.1.4.6

Training dataset	IU→EN	EN→IU
Authentic (baseline)	20.10	9.52
Transfer from CS–EN	22.98	10.41
Synthetic + auth	20.91	-
Authentic only	25.38	-

Table 2: Test set BLEU scores of our setup. Except for the baseline, each column shows improvements obtained after fine-tuning a model one line up on different datasets.

improvement of almost 3 BLEU. For a model, where we used a mix of "synthetic and authentic" data that is generated by our EN→IU model, we can notice a performance dropped from 22.98 to 20.91. However, following with fine-tuning this model again with authentic data, we get an increase in performance to 25.38. This is unexpected behaviour. Our understanding is that it could be attributed to a narrow domain of train and testset containing mainly speech transcripts. At the same time, the synthetic data are generated from English news articles, which is a more general domain. Therefore, while the model is trained on the general domain, it loses score on a domain-specific testset. This could be tested if we could obtain a testset on a different domain than speech transcription; however, we do not have such testset available.

During training on synthetic data, the model learns a general domain and loses performance on domain-specific testset to 20.91 BLEU, however after fine-tuning again on authentic domain-specific data only it reaches the highest performance of 25.38 BLEU.

4 Conclusion

We participated in the low-resource Inuktitut–English in the WMT 2020 News Translation Shared Task. We combined transfer learning with the back-translation and obtained significant improvements.

Surprisingly, we found out that although training the model on backtranslated data decreases the performance of the system in terms of BLEU score; it is still helpful when continued with fine-tuning on authentic data. We believe this is mainly because the Inuktitut–English training and test data are from a narrow domain of legal texts.

Abstract

This paper describes Tilde's submission to the WMT2020 shared task on news translation for both directions of the English↔Polish language pair in both the constrained and the unconstrained tracks. We follow our submissions form the previous years and build our baseline systems to be morphologically motivated sub-word unit-based Transformer base models that we train using the Marian machine translation toolkit. Additionally, we experiment with different parallel and monolingual data selection schemes, as well as sampled back-translation. Our final models are ensembles of Transformer base and Transformer big models which feature right-to-left re-ranking.

1 Introduction

This year, we developed both constrained and unconstrained NMT systems for the English↔Polish language pair. We base our methods on the submissions of the previous years (Pinnis et al., 2017b, 2018, 2019) including methods for parallel data filtering from Pinnis (2018). Specifically, we lean on Pinnis (2018) and Junczys-Dowmunt (2018) for data selection and filtering, (Pinnis et al., 2017b) for morphologically motivated sub-word units and synthetic data generation, Edunov et al. (2018) for sampled back-translation and finally Morishita et al. (2018) for re-ranking with right-to-left models. We use the Marian toolkit (Junczys-Dowmunt et al., 2018) to train models of Transformer architecture (Vaswani et al., 2017).

Although document level NMT as showcased by (Junczys-Dowmunt, 2019) have yielded promising results for the English-German language pair, we were not able to collect sufficient document level data for the English-Polish language pair. As a result, all our systems this year translate individual sentences.

The paper is further structured as follows: Section 2 describes the data used to train our NMT systems, Section 3 describes our efforts to identify the best-performing recipes for training of our final systems, Section 5 summarises the results of our final systems, and Section 6 concludes the paper.

2 Data

For training of the constrained NMT systems, we used data from the WMT 2020 shared task on news translation[1]. For unconstrained systems, we used data from the Tilde Data Library[2]. The 10 largest publicly available datasets that were used to train the unconstrained systems were Open Subtitles from the Opus corpus (Tiedemann, 2016), ParaCrawl (Banón et al., 2020) (although it was discarded due to noise found in the corpus), DGT Translation Memories (Steinberger et al., 2012), Microsoft Translation and User Interface Strings Glossaries[3] from multiple releases up to 2018, the Tilde MODEL corpus (Rozis and Skadiņš, 2017), WikiMatrix (Schwenk et al., 2019), Digital Corpus of the European Parliament (Hajlaoui et al., 2014), JRC-Acquis (Steinberger et al., 2006), Europarl (Koehn, 2005), and the QCRI Educational Domain Corpus (Abdelali et al., 2014).

2.1 Data Filtering and Pre-Processing

First, we filtered data using Tilde's parallel data filtering methods (Pinnis, 2018) that allow discarding sentence pairs that are corrupted, have low content overlap, feature wrong language content, feature too high non-letter ratio, etc. The exact filter configuration is defined in the paper by (Pinnis, 2018).

Then, we pre-processed all data using Tilde's parallel data pre-processing workflow that nor-

Scenario	Lang. pair	Raw	Filtered	
			Tilde	+DCCEF
(c)	En → Pl	10.8M	6.5M	4.3M
	Pl → En			4.3M
(u)	En → Pl	55.4M	31.5M	23.3M
	Pl → En			24.1M
(u) w/o PC	En → Pl	48.8M	27.0M	21.6M
	Pl → En			21.3M

Table 1: Parallel data statistics before and after filtering. (c) - constrained, (u) - unconstrained, "w/o PC" - "without ParaCrawl".

malizes punctuation (quotation marks, apostrophes, decodes HTML entities, etc.), identifies non-translatable entities and replaces them with placeholders (e.g., e-mail addresses, Web site addresses, XML tags, etc.), tokenises the text using Tilde's regular expression-based tokeniser, and applies true-casing.

In preliminary experiments, we identified also that morphology-driven word splitting (Pinnis et al., 2017a) for English↔Polish allowed us to increase translation quality by approximately 1 BLEU point. The finding complies with our findings from previous years (Pinnis et al., 2018, 2017b). Therefore, we applied morphology-driven word splitting also for this year's experiments.

Then, we trained baseline NMT models (see Section 3.2) and language models, which are necessary for dual conditional cross-entropy filtering (DCCEF) (Junczys-Dowmunt, 2018) in order to select parallel data that is more similar to the news domain (for usefulness of DCCEF, refer to Section 3.3). For in-domain (i.e., news) and out-of-domain language model training, we used four monolingual datasets of 3.7M and 10.6M sentences[4] for the constrained and unconstrained scenarios respectively. Once the models were trained, We filtered parallel data using DCCEF. The parallel data statistics before and after filtering are given in Table 1.

For our final systems, we also generated synthetic data by randomly replacing one to three content words on both source and target sides with unknown token identifiers. This has shown to increase robustness of NMT systems when dealing with rare or unknown phenomena (Pinnis et al., 2017a). This process almost doubles the size of the corpora, therefore, this was not done for the datasets that were used for the experiments documented in Section 3.

For backtranslation experiments, we used all available monolingual data from the WMT shared task on news translation. In order to make use of the Polish CommonCrawl corpus, we scored sentences using the in-domain language models and selected top-scoring sentences as additional monolingual data for back-translation.

Many of the data processing steps were sped up via parallelization with GNU Parallel (Tange, 2011).

3 Experiments

In this section, we describe the details of the methods used and experiments performed to identify the best-performing recipes for training of Tilde's NMT systems for the WMT 2020 shared task on news translation. All experiments that are described in this section were carried out on the constrained datasets unless specifically indicated that also unconstrained datasets were used.

3.1 NMT architecture

All NMT systems that are described further have the Transformer architecture (Vaswani et al., 2017). We trained the systems using the Marian toolkit (Junczys-Dowmunt et al., 2018). The Transformer *base* model configuration was used throughout the experiments except for the experiments with the *big* model configuration that are described in Section 5. We used gradient accumulation over multiple physical batches (the *--optimizer-delay* parameter in Marian) to increase the effective batch size to around 1600 sentences in the *base* model experiments and 1000 sentences in *big* model experiments. The Adam optimizer with a learning rate of 0.0005 and with 1600 warm-up update steps (i.e., the learning rate linearly rises during warm-up; afterwards decays proportionally to the inverse of the square root of the step number) was used. For language model training, a learning rate of 0.0003 was used.

3.2 Baseline models

We trained baseline models using the Transformer *base* configuration as defined in Section 3.1. The validation results for the baseline NMT systems are provided in Table 2. As we noticed last year that the ParaCrawl corpus contained a large proportion (by our estimates up to 50%) (Pinnis et al., 2019)

[4]The sizes correspond to the smallest monolingual in-domain dataset, which in both cases were news in Polish. For other datasets, random sub-sets were selected.

System	En → Pl	Pl → En
Constrained		
Baseline	21.67	32.69
+DCCEF	**22.19**	**33.45**
Unconstrained		
Baseline	21.86	**33.08**
+DCCEF	22.51	30.86
Baseline w/o ParaCrawl	**24.29**	29.47
+DCCEF	22.60	28.59

Table 2: Comparison of baseline NMT systems trained on data that were prepared with and without DCCEF.

of machine translated content, we trained baseline systems with and without ParaCrawl. It can be seen that when training the En → Pl unconstrained system using ParaCrawl, we loose over 2 BLEU points. This is because most machine translated content is on the non-English (in this case Polish) side. For the Pl → En direction, the machine-translated content acts as back-translated data and, therefore, does not result in quality degradation. Further, our Pl → En systems are trained using ParaCrawl, and En → Pl systems – without ParaCrawl.

3.3 Dual Conditional Cross-Entropy Filtering

After the baseline systems, we analysed whether DCCEF allows improving translation quality. The validation results in Table 2 show that translation quality increases for the constrained systems, but degrades for the unconstrained systems. Further, we used DCCEF only for the constrained scenario systems.

3.4 Back-translation

We used monolingual data back-translation to adapt the NMT systems to the news domain. Edunov et al. (2018) has shown that using output sampling instead of beam-search during back-translation yields better-performing NMT systems. Hence, we exclusively used output sampling for monolingual data back-translation. However, due to the abundance of monolingual data for both translation directions, we experimented with different rates of upsampling and back-translated data cutoff to determine whether translation performance doesn't degrade in the presence of a too small proportion of bitext data during training.

Another dimension of inquiry was with different strategies for data filtering in the preparation of the back-translated data. Ng et al. (2019) have described a method for domain data extraction from general domain monolingual data using domain and out-of-domain language models. We compared said method with a simpler alternative of using only an in-domain language model for in-domain data scoring. We sorted the monolingual data according to the scores produced by the in-domain language model or by the combination of in-domain and out-of-domain language model scores and experimented with different cutoff points when selecting data for back-translation.

Considering the above, we carried out experiments along two dimensions – 1) monolingual data selection strategy, which was either *combined* or *in-domain*, signifying whether the combined score of both language models or just the score from the in-domain language model was used, respectively, and 2) the bitext and synthetic data mixture selection strategy, which was one of:

- *original ratio* – all available bitext data for the translation direction were combined with all back-translated data having a score ≥ 0, when using the *combined* selection strategy, or N top-scoring back-translated sentences, when using the *in-domain* selection strategy, where N was selected to match the amount of synthetic data selected in the *combined* case.

- *upsampled 1:1* – the same amount of synthetic data was selected as with the *original ratio* data mixture selection strategy, but bitext was upsampled to match the amount of synthetic data.

- *cutoff* {*1:1, 1:2, 1:3*} – all available bitext data for the translation direction were combined with N top-scoring back-translated sentences where N was chosen so that the ratio of bitext to synthetic data was either 1:1, 1:2 or 1:3.

As a result of the above, we ended up with 96.8M sentences (14% retained) from the English monolingual corpus and 137M (99% retained) sentences from the Polish monolingual corpus after applying the *combined* data selection strategy. Consequently, the same amount of data was selected for the *in-domain* data selection strategy in the case of *original ratio* and *upsampled 1:1* data mixture selection strategies (i.e. when not doing *cutoff*).

	orig. ratio	ups. 1:1	cutoff		
			1:1	1:2	1:3
En → Pl					
combined	23.35	24.01	24.52	24.72	-
in-domain	22.10	22.92	25.02	**25.28**	25.24
Pl → En					
combined	31.19	33.45	33.29	**33.60**	-
in-domain	29.67	-	33.40	33.28	-

Table 3: En → Pl back-translation experiment results.

The results for back-translation experiments are presented in Table 3. The systems use the DCCEF-filtered constrained datasets and therefore are directly comparable to the constrained DCCEF systems in Table 2.

For our final systems, we use the *combined* selection strategy for Pl → En and the *in-domain* selection strategy for En → Pl. For unconstrained systems, we identified that there is no significant difference between translation quality; we used the *combined* selection strategy for both language pairs.

3.5 QHAdam optimizer

Last year (Pinnis et al., 2019) we used the QHAdam optimizer (Ma and Yarats, 2018) for model training, however, we hadn't treated QHAdam and Adam the same in the experimental process, having dedicated substantially more effort to optimizer hyperparameter tuning for QHAdam than Adam. To make an unbiased comparison of the two optimizers, we trained corresponding system variants using QHAdam for the *combined cutoff 1:2*, *in-domain cutoff 1:2* and *in-domain cutoff 1:3* systems from Section 3.4 in the En → Pl translation direction. The BLEU scores for the experiments are found in Table 4. We see that QHAdam performs no better than Adam. We had also done more extensive experiments comparing QHAdam to Adam for a range of learning rate and warm-up step parameter settings on a different dataset, which showed a similar trend, however we do not present those results here. As a result, we didn't choose QHAdam over Adam in this year's competition.

We note, however, that we used the recommended safe defaults for the QHAdam's hyperparameters – $v_1 = 0.8, v_2 = 0.7$ – and we haven't performed a search over these values which could have yielded different results.

	combined cutoff 1:2	in-domain cutoff	
		1:2	1:3
Adam	24.72	**25.28**	**25.24**
QHAdam	**24.86**	24.98	25.00

Table 4: BLEU scores for the QHAdam experiments in the En → Pl translation direction.

3.6 Right-to-Left Re-Ranking

Morishita et al. (2018) report improving the translation performance by using right-to-left (R2L) reranking. The method employs a right-to-left model to re-score the n-best list outputs of a regular – left-to-right – model by multiplying both models' translation probabilities. We implement R2L reranking the same as Morishita et al. (2018), but opted to use n-best lists with $n = 12$ (instead of $n = 10$).

The R2L re-ranking experiments were performed during the final stages of the competition, hence the baseline systems for those experiments were the final systems that were being prepared for submission to the news translation task. Therefore we present the results in Table 5 in the Results section. We find similar improvements as Morishita et al. (2018), albeit they are slightly smaller.

4 Final Systems

We chose the best performing system variants from Section 3 to serve as a base for the final submission for the news translation task. For the constrained scenario, we trained final systems using parallel data that were filtered with Tilde's filtering methods and DCCEF, back-translated monolingual data using a ratio of 1:2 (different data selection methods were applied for both translation directions), and synthetic data featuring unknown phenomena. For the unconstrained scenario, we trained final systems using parallel data that were filtered only with Tilde's filtering methods, back-translated monolingual data that were selected using the *combined* data selection strategy using a ratio of 1:1, and synthetic data featuring unknown phenomena. All models were trained using the Adam optimiser.

When preparing the final systems, we also employed R2L re-ranking (see Section 3.6), ensembling of the best three models, and trained Transformer models using the *big* model configuration.

	Constrained	Unconstrained
Pl → En		
Base	33.48	32.63
+R2L	34.34	33.29
Big	33.79	33.15
+R2L	**34.83**	33.45
Ensemble of 3	34.19	33.39
+R2L	34.80	33.53
En → Pl		
Base	25.64	26.12
+R2L	26.24	26.52
Big	25.59	26.47
+R2L	26.70	26.78
Ensemble of 3	26.07	26.86
+R2L	26.73	**27.12**

Table 5: Final system evaluation results (BLEU scores) on validation data (bold marks best scores; submitted systems are underlined).

5 Results

The BLEU scores for the systems that were evaluated for the final submission are shown in Table 5. The results show that right-to-left reranking increased translation quality for all systems. For the En → Pl translation direction, the best results were achieved when using ensembles of three models and better results were achieved by the unconstrained systems. However, for the Pl → En translation direction, the unconstrained systems achieved lower results than the constrained systems. The best results were achieved by the Transformer big model; ensembling did not improve results.

In overall, the results differ from what we have observed in previous years. Back-translation for Pl → En did not improve results, which raises a question of a possible domain mismatch between the monolingual data we back-translated and the development data. Unconstrained systems are only slightly better than constrained systems for En → Pl and even subpar for the Pl → En translation direction, which shows that current NMT methods are not able to benefit from larger datasets. Hence, having in-domain data is more important.

6 Conclusion

In this paper, we described Tilde's NMT systems for the WMT shared task on news translation. This year, we trained constrained and unconstrained systems for the English↔Polish language pair. We detailed the methods applied and the training recipes.

During our experiments, we identified several avenues of possible further research. We saw that larger datasets even after applying data selection methods did not allow improving translation quality (at least not significantly). We made a similar observation also previous years when participating in WMT. We saw in our results also that back-trannslation did not yield positive results for En → Pl. We hypothesise that there may be a domain mismatch between the data we used for training and the newsdev2020 dataset. However, this requires further investigation.

Abstract

This paper describes the submission to the WMT20 shared news translation task by Samsung R&D Institute Poland. We submitted systems for six language directions: English to Czech, Czech to English, English to Polish, Polish to English, English to Inuktitut and Inuktitut to English. For each, we trained a single-direction model. However, directions including English, Polish and Czech were derived from a common multilingual base, which was later fine-tuned on each particular direction. For all the translation directions, we used a similar training regime, with iterative training corpora improvement through back-translation and model ensembling. For the En $\rightarrow$ Cs direction, we additionally leveraged document-level information by re-ranking the beam output with a separate model.

1 Introduction

Since the Transformer architecture became the standard model in Neural Machine Translation, recent advancements in the field have come from two techniques. The first one is deepening the model by adding more layers, mainly in the encoder part, in order to model more complex dependencies (Raganato and Tiedemann, 2018; Wang et al., 2019a; Wu et al., 2019). This, however, poses problems during the training – too deep models are much harder to train due to the gradient vanishing problem (Zhang et al., 2019). The second technique consists in improving the quality of training data by removing spurious translations (Koehn et al., 2019) and making the data easier to learn through the teacher-student methodology (Hinton et al., 2015; Kim and Rush, 2016; Tan et al., 2019).

In this submission, we decided to leverage both techniques. We deepened the model with a lexical-shortcuts transformer modification. We also iteratively improved the synthetic corpora by training better and better translation models, back-translating and distilling the data in each step.

The remainder of this paper is structured as follows: Section 2 introduces the data used for training, Section 3 shows baseline NMT models and our experiments. In Section 4 we describe our training regime and results. Section 5 is for conclusions.

2 Data

2.1 Data Filtering

We used all the parallel data available in the constrained settings. We filtered the parallel data with a two-step process. First, we used a simple heuristics for general clean-up:

- remove pairs where any of the sentences is longer than 1500 characters
- remove sentences with characters not in the Unicode range specific to a given language pair
- remove pairs based on a length-ratio threshold.

We then de-duplicated the data and used the fast-align[1] tool to filter out pairs basing on the alignment probability between the source and the target (Table 1). For monolingual data, we used only the general clean-up procedure.

2.2 Data Pre-Processing

We used the `normalize-punctuation.perl`[2] script from the Moses package on all the training data. For the En $\leftrightarrow$ Iu directions, we used the alignment provided by the organizers, and

Proceedings of the 5th Conference on Machine Translation (WMT), pages 181–190

	Orig.	+ clean-up	+ fast-align
En ↔ Cs	62.5M	61.8M	43.4M
En ↔ Iu	2.6M	1.2M	1.1M
En ↔ Pl	11.2M	10.7M	8.6M

Table 1: Number of sentences in the parallel corpus originally, after simple rule-based cleaning-up, and after filtering out sentence pairs based on alignment probability.

decided to stick to the Inuktitut syllabics, without romanization.

For tokenization and segmentation, we used SentencePiece[3] (Kudo and Richardson, 2018). For the En ↔ Cs and En ↔ Pl directions, we started with a multilingual translation model that was later specialized towards each direction separately. For these 3 languages, we had to use a single, joint vocabulary with $32,000$ pieces and a unigram language model (ULM) tokenization scheme. For the En ↔ Iu directions, we used a joint vocabulary with the ULM tokenization scheme and $16,000$ pieces.

3 NMT System Overwiev

All of our systems are trained with the Marian NMT[4] (Junczys-Dowmunt et al., 2018) framework.

3.1 Baseline systems for En ↔ Cs and En ↔ Pl

We started with strong baselines, i.e. transformer models (Vaswani et al., 2017), which we will now refer to as *transformer-big*. This model consists of 6 encoder layers, 6 decoder layers, 16 heads, a model/embedding dimension of 1024 and a feed-forward layer dimension of 4096.

The model is regularized with a dropout between transformer layers of 0.2 and a label smoothing of 0.1. We also used layer normalization (Lei Ba et al., 2016) and tied the weights of the target-side embedding and the transpose of the output weight matrix, as well as source- and target-side embeddings (Press and Wolf, 2017). Optimizer delay was used to simulate bigger batches, updating weights every 16 batches, Adam (Kingma and Ba, 2015) was used as an optimizer, parametrized with a learning rate of 0.0003 and linear warm-up for the initial $32,000$ updates with subsequent inverted squared decay.

For each language pair, we trained both uni- and bi-directional models. We also examined the effect of using multilingual data to train a quadro-directional model on concatenated En ↔ Cs and En ↔ Pl corpora. The En ↔ Pl corpora were upsampled 5 times to match size. <*2XX*> tokens were appended to each sentence to indicate the target language. The results on newsdev2020 are presented in Table 2.

[3] github.com/google/sentencepiece
[4] github.com/marian-nmt/marian

	Uni	Bi	Quadro	Quadro-huge
En → Cs	26.1	25.4	24.4	26.0
Cs → En	32.4	31.4	30.5	32.7
En → Pl	26.1	25.4	26.2	27.3
Pl → En	30.0	30.3	31.0	32.3

Table 2: SacreBLEU scores on newsdev2020 for baseline trainings, for various model capacities: uni-directional models, bi-directional models and quadro-directional transformer-big. Quadro-huge stands for the quadro-directional model with the transformer-huge parameters.

	Corpora size	Pre-training	BLEU
En → Pl	0.25M	√	20.4
	0.25M	-	16.5
	0.5M	√	21.8
	0.5M	-	19.4
	8.6M	√	25.1
	8.6M	-	26.1
Pl → En	1M	√	27.1
	1M	-	25.7
	8.6M	√	29.1
	8.6M	-	30.0

Table 3: SacreBLEU scores on newsdev2020 for En ↔ Pl trainings, with and without pre-training. 8.6M corpora size means all the available training data was used.

3.2 Baseline system for En ↔ Iu

As the parallel corpora for En ↔ Iu are significantly smaller than for the other pairs, we decided to start with a transformer model with a smaller number of parameters i.e. *transformer-base*. All our base models were bi-directional.

The model consists of 6 encoder layers, 6 decoder layers, 8 heads, a model/embedding dimension of 512 and a feed-forward layer dimension of 2048. We examined the effect of vocabulary size on the model quality, and obtained the best results for the vocabulary size of $16,000$ (Table 4). Basing on our previous experience, we also examined an

	Vocab size	BLEU
En → Iu	16k	15.1
	32k	15.1
	64k	15.0
Iu → En	16k	28.3
	32k	27.9
	64k	27.6

Table 4: SacreBLEU scores on newsdev2020 for En ↔ Iu bi-directional trainings, for different sizes of the sentencepiece vocabulary.

unbalanced encoder/decoder configuration with a deeper encoder (8 layers) and a more shallow decoder (4 layers). The result was 28.3 (+0.0) for Iu → En and 15.3 (+0.2) for En → Iu, compared to the base case. We used this model as a reference for the following experiments.

3.3 Multilingual Denoising Pre-training

Liu et al. (2020) recently proposed a method for pre-training sequence-to-sequence models with an auto-encoder-based denoising objective. Pre-training a complete encoder-decoder model allows for later direct fine-tuning on the translation objective, with parallel corpora. In our experiment, we sampled 250M sentences from CommonCrawl for Czech, English and Polish (i.e. 750M in total). During training, we randomly cropped up to 25% tokens from each sentence, and taught the model to predict the original sequence. We used the same architecture as in baseline trainings. Next, we used the best checkpoint to warm-start training on the parallel data. Table 3 presents our results for varying sizes of the training corpus (the smaller corpus is a random subset of the parallel data). We observe that, although our implementation works well for low-resource setting, it leads to quality drop when all the parallel data is used. Accordlingly, we used this pre-training method only for the En ↔ Iu directions.

3.4 Lexical Shortcuts

Since our quadro-directional model showed promising results, we decided to try to examine the effect of deepening and enlarging the model. We increased the feed-forward layer dimension to 8192, and the number of encoder layers to 12. The rest of the parameters is the same as in *transformer-big*. He et al. (2019) demonstrated that, with a fixed number of layers, it was more efficient to have a deeper encoder than decoder. It also makes decoding for back-translation much faster. To help with gradient propagation, we implemented Lexical Shortcuts (Emelin et al., 2019) in the encoder. We used the feature-fusion version of the gating mechanism. The results are summarized in the Quadro-huge column in Table 2. This model outperformed the baseline in all the directions, except one. We decided to use this system in further trainings.

	Pl	En	Cs
Newscrawl	3.7M	230M	80.5M
+ Moore-Lewis	96.5M	-	-

Table 5: Number of sentences in monolingual datasets after clean-up and domain-based filtering.

3.5 Back-Translation with Language Model

Back-translation (Sennrich et al., 2016) is a common strategy of utilizing monolingual data in training NMT systems. For English and Czech, the amount of monolingual in-domain data in the Newscrawl data set is big enough, so for this language pair we used only the monolingual set. Yet for Polish, the Newscrawl is very limited in size, hence we decided to use Moore-Lewis filtering (Moore and Lewis, 2010) to extract in-domain data from CommonCrawl.

With this additional monolingual corpus, we had over 80M in-domain news sentences for each language (Table 5). We used those monolingual datasets to train an in-domain RNN-style language model for each of the three languages, using the same common vocabulary as the one in the translation models. This allowed us to easily ensemble this language model with a translation model during decoding, as described in Gulcehre et al. (2015). For each iteration of the back-translation, we used an ensemble of the top 4 NMT models available w.r.t. the dev-set score for the particular direction and the in-domain language model. The weights of the models were optimized through a grid-search.

3.6 Noisy Channel Model Reranking

Re-ranking the beam output is a method used to improve translation quality by the re-scoring hypothesis from a forward model. The noisy channel model (Yee et al., 2019) approach was used with success by Facebook in their submission to the WMT19 news translation task (Ng et al., 2019). Based on the Bayes' rule, given a target sequence y and a source sentence x, for every hypothesis from

the beam output, we calculate

$$\log P(y \mid x) + \lambda_1 \log P(x \mid y) + \lambda_2 \log P(y)$$

and use this score to re-rank the beam outputs. We model $P(y \mid x)$ with the forward model, $P(x \mid y)$ with the backward model and $P(y)$ with the language domain model. The weights λ_1 and λ_2 are tuned on the dev-set.

When we used this method for our baseline unidirectional systems, we noticed significant BLEU improvements: 26.9 (+0.8) on newsdev2020 for the En → Pl direction. However, there was no improvement when applied to translations produced with strong ensembles of both the domain language models and the translation models, trained on the back-translated data. In our final submission, we used this method only for the Iu → En and En → Iu directions.

3.7 Multi-Agent Dual Learning

In our submission, we used the simplified version of Multi-Agent Dual Learning (MADL) (Wang et al., 2019b), proposed in Kim et al. (2019), to generate additional training data from the parallel corpus. We generated n-best translations of both the source and the target sides of the parallel data, with strong ensembles of, respectively, the forward and the backward models. Next, we picked the best translation from among n candidates w.r.t. the sentence-level BLEU score. Thanks to these steps, we tripled the number of sentences by combining three types of datasets:

1. original source – original target,
2. original source – synthetic target,
3. synthetic source – original target,

where the synthetic target is the translation of the original source with the forward model, and the synthetic source is the translation of the original target with the backward model.

3.8 Document Level Reranking

For the En ↔ Cs translation directions, the training data is aligned on the document level. To make use of this information, we implemented the method presented in Voita et al. (2019). The method assumes one has access to consecutive tuples of sentences in the target language. Using the backward and forward models, one should translate the tuples with the sentence-level based systems, and then train the model to predict the original tuple, basing on the two-way translated data. As we already have access to the document-level aligned translations from the CzEng 2.0 corpus (Kocmi et al., 2020), we could do the translation just once. We experimented only with the En → Cs direction. We selected tuples of 4 consecutive sentences in English, translated each sentence independently, and glued the translations back together. We used a special token to indicate the end of the sentence. See Table 9 in the Appendix for an example of the training data. However, when we utilized this model to "repair" the newsdev2020 dev-set translations, we noticed a quality drop. We decided to try a different approach, and used the document-level repair model to re-rank the beam output. The procedure is similar to a greedy search for the best path through n-best lists of forward model translations. It is described with Algorithm 1.

Algorithm 1 Document Level Reranking

Input: $\{trn^b(s_j)\}$ - n-best list ($b = 1..N$) with translations of sentence s_j

Input: $L_{repair}(\{sa_j\}_{j=1..4}, \{sb_j\}_{j=1..4})$− likelihood computed with repair model for two 4-sentence sequences

Output: Re-ranked translations rep

for all paragraph in test-set **do**
  $i = 0$
  for all sentence s_i in paragraph **do**
    if $i < 4$ **then**
      $rep_i = trn^1(s_i)$
    else
      $seq_1 = rep_{i-3}, \ldots, rep_{i-1}, trn^1(s_i)$
      $seq_b = rep_{i-3}, \ldots, rep_{i-1}, trn^b(s_i)$
      $rep_i = \arg\max_{b=1..N} L_{repair}(seq_1, seq_b)$
    end if
    $i \mathrel{+}= 1$
  end for
end for

Although on the dev-set we didn't see much difference in the BLEU score, manual inspection showed some promising results. We decided to apply this method to our best-scoring system and saw a 0.1 improvement in the BLEU score on the test-set.

3.9 Post-Processing

For all the translation directions we participated in, we normalized the system outputs with a series of

regular expressions:

- substitute English quotation marks (“ ... ”) with Czech/Polish ones („ ... ”),
- if a source starts/ends with a quotation mark, we make sure so does the translation,
- remove word repetitions,
- replace consecutive sequences of white-spaces with a single one,
- if a source ends with a punctuation mark (e.g. ?.!), we substitute the last character of the translation with it,
- replace three consecutive dots with an ellipsis,
- replace hyphens with en dashes.

4 Results

4.1 English → Polish

The model for the English → Polish direction was derived from the multilingual quadro-huge model – similarly to the other models for directions with Polish, Czech or English. The successive steps and respective BLEU scores are reported in Table 6.

We started with fine-tuning the quadro-directional model on the parallel data for the specific direction. Next, we used an ensemble of our best models to back-translate Newscrawl 2018 and 2019, we filtered it (3.5M sentences) and merged with the parallel corpus (8.6M). The fine-tuning gave us +1.5 BLEU improvement. We were able to achieve an additional +0.9 BLEU with the rule-based post-processing (see above). In the next step, we used the MADL procedure to generate additional data. To further increase the amount of data and its variability, we picked the top 2 best translations, according to the sentence-level BLEU in the distillation process – instead of choosing just one. Again, we up-sampled the original parallel corpus twice. This procedure gave additional 52M sentences (a 6-fold increase).

We back-translated all the monolingual in-domain data (i.e. 89M after filtration) and used both corpora to fine-tune the next generation model. We augmented the data by randomly masking up to 10% of the input tokens with a random punctuation mark, and observed yet another performance boost. Using all these corpora, we trained another model from scratch, hoping to get a less correlated model.

WMT'20 SUBMISSION	**27.6**	**34.3**

Table 6: Successive improvements in the BLEU scores on the English → Polish and Polish → English directions, computed with SacreBLEU.

Although the fresh model performance was poorer than the previous best (30.2 BLEU vs. 31.6 BLEU), the grid-search ensemble optimization included it in the best ensemble. As a final step, we used Moore-Lewis filtering to choose 1M Newscrawl sentences that were closest to the concatenated newsdev2020 and newstest2020. We translated them with the best ensemble, and used it to fine-tune our best-performing model. Again, we ran ensemble optimization including this model into the models reservoir. The optimal ensemble was the one we submitted as the primary system.

4.2 Polish → English

For the Polish to English direction, we proceeded similarly to our solution for English to Polish. We started with the quadro-huge model. We back-translated Newscrawl 2018, filtered it (12M sentences) and merged with the parallel corpus (8.6M). We kept on training the fine-tuned quadro-huge model, increasing the performance by 0.9 BLEU. We used the same MADL procedure as before, distilling 2 best translations for each source sentence. We also back-translated Newscrawl 2007-2017 (144M) and merged it with the MADL corpus. With this corpus, single model performance increased by +0.7 BLEU. We used the same corpus to train a fresh model. Similarly to the English to Polish direction, the fresh model performed poorer

(32.9 BLEU) than the fine-tuned one (34.4 BLEU), but – again – in ensemble it gave additional improvement. Finally, we fine-tuned on the 1M corpora filtered out from Newscrawl in the domain of the concatenated newsdev2020 and newstest2020, and ensembled for the final submission.

4.3 English → Czech

We started with fine-tuning the quadro-huge model with only English to Czech parallel data and ensembling several models into one. This model specialization gave us +1.4 BLEU. Next, we back-translated Newscrawl 2018 and 2019 in two flavors: normally, and with adding Gumbel noise (`--output-sampling` in Marian). Then, we filtered the result (see section 2.1), obtaining 35M sentences. With this additional corpus, the single model performance improved by 0.9 BLEU. In contrast to the Cs → En direction, using back-translations from CzEng 2.0 seemed to hurt the model performance.

In the next iteration, we produced the MADL corpus (120M) and merged it with back-translated Newscrawl 2009-2017 (102M, with and without noise) and used this data to train yet another model. Finally, we ensembled this model with models trained from scratch and fine-tuned on the 1M from Newscrawl common with the concatenated newsdev2020 and newstest2020. Before the last step – document level re-ranking – we used the sentence-splitter from NLTK (Bird et al., 2009) to pre-process the testset. It was required because of our systems being trained with sentence-level data and in newstest2020 some of the segments contain multiple sentences. We translated the pre-processed testset with the best ensemble, re-ranked on the document level and finally glued back the translations together. The document level re-ranking gave us -0.1 BLEU on the dev-set but +0.1 on the test-set.

4.4 Czech → English

Again, the specialization of the quadro-huge model with only Czech to English data gave us almost 1 BLEU gain in performance. Next, we back-translated Newscrawl 2018 and 2019 and filtered it with our pipeline, obtaining 49M sentences. We added the Newscrawl translations from CzEng 2.0 (79M) and the original filtered parallel corpus (43M), ending up with 171M parallel sentences as our training set. Using this data, we improved the single model performance by 3.6 BLEU. Fine-tuning on the MADL corpus (120M) and the back-translated Newscrawl 2017 (25M) gave additional +1.2 BLEU on the single model. Finally, we ensembled them with a model trained from scratch and fine-tuned on the 1M sentences from Newscrawl that were similar to the concatenated newsdev2020 and newstest2020 w.r.t. the Moore-Lewis score. For sentence splitting, we used the same splitter as for En → Cs. Results on the previous test-sets of the final systems for the En ↔ Cs directions, without document level re-ranking, in the Appendix (Table 10).

4.5 English ↔ Inuktitut

In contrast to all the other directions, for Inuktitut we had much less monolingual data (10k after cleaning) than bitext (1.1M). In the first step, we back-translated the monolingual data with beam 10, and kept all the possible variants (0.1M sentences). We also back-translated the English Europarl v10 corpus (2M), because we believed it to help with the Hansard (Joanis et al., 2020) part of the dev- and test-sets. We merged it with the two-directional parallel data (2.2M) and trained a bi-directional model, from scratch. We used it for the general first iteration of the MADL corpus (6.6M), and used all of the data to once more train a model from scratch. Here we examined the effect of pre-training. We used the sample (10M)

from the English Newscrawl 2019 and the Inuktitut part of the parallel data, up-sampled 5 times (5.5M). With the pipeline approach, fine-tuning on bitext was giving us similar results as training on bitext from scratch. Nevertheless, we were however able to achieve some improvement, when training a fresh model on the merged parallel and noised monolingual data. We were able to achieve further improvement with increased model size – 1024 embedding dimension, 4096 forward dimension and 16 heads.

Next, we started fine-tuning on each direction independently, using the parallel data for En → Iu, and 20-times up-sampled the parallel data (22M) together with the back-translated Newscrawl 2018 and 2019 (48M) for Iu → En. Then, we used an ensemble of models to once again generate the MADL corpus, use it to fine-tune the unidirectional models and the ensemble once again. We used the Noisy Channel Reranking method and saw some improvement on both the dev-set and the test-set.

5 Conclusions

In this paper, we have described the submission to the WMT20 shared news translation task by Samsung R&D Institute Poland. All submitted systems were constrained and utilized only the permitted data. With our approach, we were able to leverage two important techniques that improve the translation quality. One method was deepening the model, while still being able to train it effectively. The other one was filtering and improving the quality of the training data and producing high quality synthetic data. Our iterative approach of improving the training data and improving the translation model proved to be successful, showing gradual increase in the BLEU scores.

Abstract

We describe the joint submission of the University of Edinburgh and Charles University, Prague, to the Czech/English track in the WMT 2020 Shared Task on News Translation. Our fast and compact student models distill knowledge from a larger, slower teacher. They are designed to offer a good trade-off between translation quality and inference efficiency. On the WMT 2020 Czech ↔ English test sets, they achieve translation speeds of over 700 whitespace-delimited source words per second[1] on a single CPU thread, thus making neural translation feasible on consumer hardware without a GPU.

1 Introduction

The conventional set-up of the WMT Shared Tasks on News Translation emphasizes translation quality (however measured) above all else. Constraints on the data that may be used for training in the 'constrained' track establish a level playing field in terms of the information available to the translation model and its training process, but there are no constraints on the computational power and effort spent to achieve the results. In contrast, the WNGT Shared Task on Efficient Translation (Heafield et al., 2020) encourages participants to submit systems that are both accurate and efficient during inference (i.e., translation). So far, there has been little interaction between the two tasks.

With our joint submission between the University of Edinburgh (UEDIN) and Charles University, Prague (CUNI), we strive to bridge this gap. We submitted small, efficient systems that distilled knowledge from a more powerful teacher model via sequence-level knowledge distillation (Kim and Rush, 2016). In a nutshell, the procedure can be described as follows:

1. Train a powerful teacher model on the available training data set D.
2. Translate the source side of D plus available monolingual data in the source language and appropriate text domain with the teacher model to generate the training set D'.
3. Train a small student model on D'.

While the computational effort to first train a teacher model and then distill its knowledge into a student model is considerably greater than just training the teacher — in addition to training the teacher, we have to translate the training data and then train a student on that data —, the advantage is at inference time. Even the larger of the two student models we present in this paper can translate on a single CPU core at an acceptable speed (cf. Tab. 4). Translation can further be sped up by quantizing parameters to 8 bits of precision and using Integer General Matrix Multiplication (IntGEMM) for inference. Even though our submissions to the WMT 2020 Shared Task on News Translation were produced by unquantized floating point models, we report performance numbers for quantized models as well to demonstrate their efficacy and show that they can speed up translation by about 10% with negligible trade-offs in terms of BLEU score over unquantized models.

All models used in this work are based on the Transformer architecture (Vaswani et al., 2017). Details are discussed in the sections below; the hyper-parameter settings for each model are listed in Tab. 1. The student models described in this paper can be obtained via https://github.com/browsermt/students.

2 Teacher Models

The teacher models were produced by CUNI, using the Tensor2Tensor deep-learning toolkit (Vaswani et al., 2018)[2]. The teachers were trained on the full

[1] Bogoychev et al. (2020) report translation speeds of up to 3135 source words per second on a single CPU thread; the actual throughput depends not only on the computer hardware used for translation but also on the distribution of translation segment lengths in the test set.

CzEng 2.0 dataset (Kocmi et al., 2020)[3] consisting of genuine (authentic) parallel data as well as monolingual news data translated by CUNI's transformer systems from WMT 2018 (Popel, 2018) to generate back-translated synthetic training data (Sennrich et al., 2016). Rather than shuffling and mixing authentic and synthetic training data, the teacher models were trained on alternating blocks of authentic and synthetic data ("block-regime back-translation" (block-BT); Popel et al., 2020), spending about 10 hours of training time on each block.

The model parameters for the final teacher models were obtained by checkpoint averaging over the last 8 checkpoints of the training process, saved in hourly intervals.

The en→cs teacher model used in this work also produced CUNI's primary submission to the WMT 2020 Shared Task on News Translation ("CUNI-Transformer"; Popel, 2020). However, the CUNI submission used a beam size of 4 instead of 8 as used in this work, resulting in a BLEU score on the WMT 2020 en→ test set that is 0.2 lower than the BLEU score reported in Tab. 4.

The cs→en teacher model used in this work has only 6 encoder layers as opposed to the 12 encoder layers used in CUNI's primary submission to the Shared Task, resulting in a BLEU score on the WMT 2020 test set that is 1.0 BLEU points lower than the score achieved by the model used for CUNI's primary submission.

3 Student Models

The smaller, more efficient student models were trained by UEDIN with the Marian NMT toolkit (Junczys-Dowmunt et al., 2018a)[4]. The students were trained on artificial training data produced by knowledge distillation (Kim and Rush, 2016), where the target side of the parallel data is the teacher model's translation of the source side. The basic idea is that the teacher guides the student towards translations that can be achieved with the teacher's knowledge.

3.1 Student Model Architectures

The student models use the architecture proposed by Kim et al. (2019) with improvements by Bogoychev et al. (2020). Apart from using fewer layers and fewer dimensions in each layer, the main difference of the students from the conventional transformer architecture is the use of Simpler Simple Recurrent Units (SSRU; Kim et al., 2019) instead of the self-attention mechanism in decoder part of the transformer. For the sake of simplicity, our student models use exponential smoothing of model parameters with a smoothing parameter of 0.0001 instead of the checkpoint averaging used to produce the final teacher models.

For each translation direction, we trained two models: a base transformer and a 'tiny' transformer with fewer decoder layers and a smaller number of embedding and filter dimensions; specifications are shown in Tab. 1.

3.2 Data Preparation

To create artificial training data for the students, we used the original parallel section of the CzEng 2.0 dataset but no back-translations. Instead, we translated ca. 40 million sentences from the mono-

[3] http://ufal.mff.cuni.cz/czeng

[4] https://github.com/marian-nmt/marian

Table 2: Data used for training the models (in millions of sentence pairs).

data set	teacher		student	
	cs→en	en→cs	cs→en	en→cs

Teacher-translated news			50.1m	43.0m
Top 90% according to alignment score			83.2m	76.8m
Total used	111.7m	137.3m	83.2m	76.8m

lingual English NewsCrawl corpus[5] (2018 and 2019) for en→cs and 50 million sentences from the monolingual Czech NewsCrawl corpus (2013–2019) for cs→en.

Prior to translation with the respective teacher model, we filtered and de-duplicated the data. Filtering consisted of the following steps:

- Sentence-level deduplication.
- Removal of excessively long sentences (longer than 120 space-separated tokens; note that the sentence length limit for training in terms of subword units was 200; cf Tab. 1).
- Removal of sentence pairs that were not identified as the correct language by the fastText language identifier (Joulin et al., 2017, 2016) Python module.[6]
- For parallel data, removal of sentence pairs with length ratio larger than 2.5 (in terms of words of untokenized text), i.e. the longer sentence could not be more than 2.5 times as long as the shorter one.
- Removal of sentences in which less than half the words contain an alphabetical character or less than half the characters belong to the alphabet of the specific language.

We translated the cleaned data with the Tensor2Tensor teacher model with a beam size of 8. A small proportion of 'odd' sentences that had escaped our cleaning process, for example sentences with several long URLs that resulted in very long token sequences after segmentation into subword units, forced us to use a relatively small batch size of 8–24 sentences to avoid out-of-memory errors. For load balancing, we split the translation load into blocks of 10,000 sentences each and parallelized the translation process over dozens of machines. Using comparatively many translation blocks gave us flexibility in scaling the translation operation in response to resource availability.

[5] http://data.statmt.org/news-crawl/
[6] https://pypi.org/project/fasttext/

Despite the small batch size, 32 of our 10,0000-sentence input chunks still failed to translate due to memory limitations. A cursory investigation revealed that these often contained undesirable material (such as Javascript and HTML code that had somehow survived the filtering process), so that we decided to simply discard those blocks of data.

We made no effort to optimize translation speed and throughput for the teacher models in Tensor2Tensor; translation time for a single 10,000-sentence block was ca. 30–45 minutes, depending on sentence lengths and hardware used.

Table 3: Distribution of teacher-produced translations chosen by sentence-level BLEU score over their respective ranks in the decoder beam.

rank	en→cs	cs→en
1	32.22%	31.24%
2	15.20%	15.63%
3	12.25%	12.21%
4	9.79%	9.87%
5	8.89%	8.88%
6	7.73%	7.85%
7	7.26%	7.40%
8	6.67%	6.93%

For the authentic parallel data, we selected from the 8 top-scoring final translation hypotheses for each source sentence the one with the highest sentence-level BLEU score with respect to the original target side of the data. Table 3 shows the distribution of the hypotheses selected over the respective beam ranks. For the monolingual data, for which we obviously have no human reference translations, we simply chose the highest-scoring translation. Sentence pairs where the translation contained the same whitespace-separated sequence of words three or more times in a row, or the same sequence of one or more characters in five or more subsequent repetitions (which can happen when the recursive decoder goes into a loop) were discarded.

We subsequently tokenized the synthetic teaching data (source and translations by the teacher model) with SentencePiece (Kudo and Richardson, 2018),

using a joint vocabulary for both languages with a size of 32,000 tokens. This vocabulary is also used by the final systems. The tokenized training data was word-aligned in both translation directions with FastAlign (Dyer et al., 2013). Directional word alignments were then symmetrized with the grow-diag-final-and symmetrization algorithm (Koehn et al., 2003).

These word alignments serve mainly three purposes: (a) to guide the attention mechanism during training of the student models (Liu et al., 2016) with guided alignment (Chen et al., 2016); (b) to produce shortlists of translation candidates to limit the choice of target words that need to be considered during inference (Junczys-Dowmunt et al., 2018b); and (c) to give us a rough estimate of translation quality via average per-token alignment scores for each sentence pair. We used these scores to discard the bottom 10% of our artificial training data.

Based on our experiments, the guided alignment training is neither required for student model training, nor does it improve BLEU scores on the development set. However, it encourages the guided decoder layer to mimic word alignments, which can be useful in post-processing.[7] We used default settings from Marian for the guided alignment training.

3.3 Quantized Models

Floating point operations are computationally more expensive than integer operations. However, as Han et al. (2016) have shown, neural network inference does not require the high precision of representation and computation that 32-bit floating point numbers offer. Devlin (2017) suggests a simple quantization mechanism for quantizing parameters to 16-bit integer precision and notes that support for off-the-shelf 8-bit integer matrix multiplication is lacking. Bogoychev et al. (2020) fill that gap and provide an 8-bit quantization and fine tuning scheme for Marian based on the intgemm library;[8] we used that scheme for our models. The model parameters are quantized offline from *float32* to *int8*, and during translation, the activations are quantized just prior to each GEMM operation. The GEMM operation is performed in 8-bit integers, and then the result is de-quantized back to *float32*. Despite the extra quantization and de-quantization involved, the increased speed at which 8-bit integer multiplication is performed more than compensates for it. Bogoychev et al. (2020) observe that smaller student presets lose BLEU when quantized. In order to counteract that, we perform model fine tuning following the work of Aji and Heafield (2020): We replace the GEMM routine implementation with a custom one that is damaged, according to the quantization scheme and perform several thousand mini-batch updates of the model. The damaged GEMM implementation can only produce 255 unique float values (corresponding to the 8-bit integer dequantization range) and the model quickly learns to work with those values and recovers some of the BLEU lost compared to untuned quantized model.

4 Results

In Table 4, we show the performance of the three models in terms of BLEU scores for the WMT 2020 cs↔en test sets and translation speed. Teacher models ran on an Nvidia GeForce GTX 1080 with a batch size of 16. Student models were run on a single CPU core on an Intel Intel(R) Xeon(R) CPU E5-2680 0 @ 2.70GHz with a batch size of 64. It should be noted that we made no effort to optimize the teachers for translation speed.

Text segments in the WMT 2020 cs↔en test sets are aligned at the paragraph level; we therefore split the provided segments into individual sentences prior to translation with Moses-style sentence splitting[9] and restored paragraphs afterwards.

All BLEU scores were computed with SacreBLEU.[10] For the en→cs teacher model, removing repetitions and adapting quotation marks to Czech spelling conventions boosted the BLEU score by 1.6 BLEU points; for student models, this post-processing is not necessary. Having been trained on post-processed teacher output, the student models have learned this correctly. Except where indicated, translation was with a greedy search (beam size 1) and a shortlist of 50 translation candidates per source word.

Due to resource congestion, we were not able to fully train the models by the submission deadline; our submissions are based on the systems with the best validation BLEU score available at the time. For validation, we used the concatenation of all parallel data for the respective translation direction from the WMT test sets from the years 2008 through 2019 where the original language of the data is the source language for the translation direction in question.

In terms of BLEU score on the WMT 2020 test set, the submitted primary system for cs→en is ca. 0.5 BLEU points below the final system; the en→cs system incidentally outperforms the final system by 0.5 BLEU points, as shown in Tab. 4.

[7] For example, for handling HTML tags in translated texts.

[a] Inference time for core test set without additional test sets.
[b] Beam size 8; postprocessing: remove repetitions, adapt quotation marks to Czech conventions.
[c] After 65K updates, shortlist size 100.
[d] After 190K updates, shortlist size 100.
[e] Pre-computed scaling factor for quantization, see Sec. 5.1 in Bogoychev et al. (2020) for details.

5 Conclusion

We presented student models that distill knowledge from a larger teacher model without loss in BLEU performance. (In fact, for the WMT 2020 test set, our larger student models technically outperform the teacher in terms of BLEU, but we consider that difference accidental.) At the same time, they are significantly faster and do not require a GPU for inference, making it possible to perform neural machine translation on consumer-grade hardware without the use of a GPU.

The University of Edinburgh's submission to the German-to-English and English-to-German Tracks in the WMT 2020 News Translation and Zero-shot Translation Robustness Tasks

Ulrich Germann
University of Edinburgh, UK
ugermann@inf.ed.ac.uk

Abstract

This paper describes the University of Edinburgh's Submission of German ↔ English systems to the WMT2020 Shared Tasks on News Translation and Zero-shot Robustness.

1 Introduction

This paper describes the University of Edinburgh's submission to the German-to-English and English-to-German tracks in the WMT 2020 News Translation and Zero-shot Robust translation tasks. We built our systems in three stages, loosely following the procedure by Junczys-Dowmunt (2018b). All translation models mentioned in this paper were trained with the Marian toolkit (Junczys-Dowmunt et al., 2018).

2 3-stage Build Process

We distinguish three types of training data provided for the tasks, shown in Table 1.

Table 1: Data available for training systems

corpus	sentence(pair)s
High-quality parallel data	
Europarl	ca. 1.79 M
Rapid	ca. 1.45 M
News Commentary	ca. 0.35 M
Crawled parallel data	
ParaCrawl 5.1	ca. 34.37 M
CommonCrawl	ca. 2.40 M
WikiMatrix	ca. 6.22 M
WikiTitles	ca. 1.38 M
Monolingual crawled news data	
German	ca. 327.69 M
English	ca. 233.50 M

2.1 Round 1: Training models for scoring crawled parallel data

In the first round, we trained base transformer models (Vaswani et al., 2017) with Sentence-Piece subword segmentation (Kudo and Richardson, 2018) with a joint vocabulary of 32K tokens on the high-quality parallel data. The joint vocabulary remains the same for all models. We applied a binomial sentence length model to remove from the parallel data sentence pairs with an unreasonable sentence length ratio. The model assumes that a pair of sentences of lengths K and L is produced by a series of K+L flips of a biased coin. The bias is based on the corpus-level ratio of tokens; for German and English, we determined that there are on average 1.0723 English tokens per German token, so the Null Hypothesis assumes that an English word is generated with a probability of 51.75%, and a German word with a probability of 48.25%. For each sentence pair, we determine the p-value of the Null Hypothesis; if it is less than 0.5%, the sentence pair is discarded. This sentence filtering filtered out less than 2% of the EuroParl data, ca 3.4% of the NewsCommentary data, and 11% of the Rapid corpus. The numbers given in Table 1 are after filtering.

2.2 Selecting crawled parallel data

We used these models to compute the length-normalized cross-entropy for each sentence pair in the available crawled parallel data in both translation directions, and combined these two entropies into the dual cross-entropy score (Junczys-Dowmunt, 2018a). To bias data selection towards the news domain, we also computed length-normalized cross-entropy for each sentence with a 5-gram language model[1] trained on the respective monolingual news data for the target side and added the two scores to obtain a single score for ranking candidates. The top n candidates from the crawled parallel data were pooled with the high-quality parallel data for the second round of training. We experimented with the top 15 M, top 20 M, and top 25 M candidates from the pool of crawled parallel data. We did not put effort into cleaning or filtering the data prior to scoring, as we assumed that poor candidates would be detected by the dual cross-entropy score.

[1] https://github.com/kpu/kenlm

Proceedings of the 5th Conference on Machine Translation (WMT), pages 197–201
Online, November 19–20, 2020.

For the German-to-English system, we unfortunately committed a serious blunder that we did not notice until shortly before submitting this system description: instead of sorting in descending order of ranking score, we accidentally sorted in descending order of provenance label first and (also lexicographically) ranking score second, so that for the translation direction German→English, the crawled data selection contained all of WikiMatrix data, none of the CommonCrawl data, and a selection of ParaCrawl data. The selection error rate in the Top-25M confiuration is ca 66% (i.e., 66% of that data should not have been selected, and we missed 66% of the data that we wanted to select). As we used Round2-models for back-translation of monolingual data, this error may have also tainted the training of the English-to-German system.

2.3 Round 2: Big transformers for back-translation

We then trained big transformer models for back-translation of monolingual news data, using the "top" (see above for our blunder on German-to-English data selection) 25M candidates.

2.4 Back-translation of news data

We used single models to translate all of the news data for German and English, adding a bit of noise in the translation by adding Gumbel noise to the output layer, thus adding some randomness to the translation process.

2.5 Round 3: Training final models with back-translation.

In the final round of training, we trained big transformer models on a blend of back-translated data (75%), crawled parallel data (15%) and high-quality parallel data (10%). Due to the volume of training data available for this round, we replaced full shuffling of the data for each epoch by random selection: we loop over each data source, fully shuffling the latter two data sources (crawled and high-quality parallel) in each iteration, but shuffling the backtranslated news data only once and then randomly selecting only 10% of the data in each iteration. Reading separately from the three data sources, the data feeder randomly selects one data source at a time according to the aforementioned distribution of 75,15, and 10% and outputs the next sentence pair in the queue.

3 Training details

For training, we experimented with variations on learning rate, batch size, warmup, and norm clipping. Due to an apparent bug in the implementation of norm clipping in Marian,[2] the Marian authors do currently not recommend to use norm clipping with Marian.[3] However, we found that without it, training would occasionally fail due to exploding gradients. Norm clipping also allowed us to be more agressive with the learning rate,

Settings and BLEU scores[4] on the validation set (WMT19) are shown in Table 2. Effective batch size was influenced by the GPU memory allocated and the number of gradients accumulated before a parameter update ("optimizer delay"). In principle, doubling the optimizer delay should double the batch size, but we found this not to be the case in practice. An analysis after the fact revealed that this was due to interactions between automatically fitting batch sizes to available memory (`--maxi-batch-fit`), setting maxibatch size, and the optimizer delay parameter that are currently not documented well for the Marian toolkit and that we misunderstood.

For German-to-English, training on back-translated data did not lead to improvements in terms of BLEU on the validation set, so we ensembled the 4 listed round-2 models for our primary submission. We were able to boost the BLEU score of the raw translation output by 1.3 BLEU points with a simple post-processing step that simply adjusts quotations marks to German spelling conventions.

For English-to-German, we submitted an ensemble of the 8 round-2 models with the highest BLEU score with respect to the validation set (WMT19).

Here, too, training on back-translated news data did not lead to an improvement over the best Round-2 model, so that we did not use any round-3 model for the final submission. We were able to boost performance by increasing the batch size during training, which is in line with our findings from last year (Bawden et al., 2019), but the effect was much smaller this year. This may be due to the fact that the initial model (#10, English→German) was already trained with a fairly large batch size.

4 Results

Table 3 shows the overlap (as measured in BLEU) for all primary systems submissions to the News Translation Task as released by the workshop organizers. We notice a few things. First, our data selection blunder for the German-to-English system has not catastrophically harmed final performance. In fact, in terms of ranking with respect to BLEU, our German-to-English system does better than our English-to-German system.

[2] Gradients aren't normalized but norm clipping isn't adjusted for batch size.

[3] Personal communication with R. Grundkiewicz.

[4] All BLEU scores reported in this paper were computed with SacreBLEU (Post, 2018); BLEU+case.mixed+numrefs.1+smooth.exp+tok.13a +version.1.4.14.

de→en set 1	38.8
de→en set 3	43.8

Second, the difference between the independently created human reference translations (REF1 and REF2) is larger than the difference between the top-performing automatic translations and either of the systems. We conjecture that is is due to the fact that individual translators will have individual translation styles, whereas automatically trained systems learn to emulate the "average" translator. However, this once again raises the question about the validity of BLEU as a measure of translation quality.

Third, we find the high overlap between the top-scoring automatic systems remarkable. This suggests that under the constrained conditions, independently systems do learn a very similar style of translation.

For the Zero-shot Robustness Task, we used the same systems as for for the News Translation Task. We report BLEU scores for the Zero-Shot Robustness Task in Table 4.

Abstract

We describe our submission for the English→Tamil and Tamil→English news translation shared task. In this submission, we focus on exploring if a low-resource language (Tamil) can benefit from a high-resource language (Hindi) with which it shares contact relatedness. We show utilizing contact relatedness via multilingual NMT can significantly improve translation quality for English-Tamil translation.

1 Introduction

In recent years, Neural Machine Translation (Luong et al., 2015; Bahdanau et al., 2015; Johnson et al., 2017; Wu et al., 2018; Vaswani et al., 2017) (NMT) has become the most prominent approach to Machine Translation (MT) due to its simplicity, generality and effectiveness. In NMT, a single neural network often consisting of an encoder and a decoder is used to directly maximize the conditional probabilities of target sentences given the source sentences in an end-to-end paradigm. NMT models have been shown to surpass the performance of previously dominant statistical machine translation (SMT) (Koehn, 2009) on many well-established translation tasks. However, in order to obtain good translation quality, NMT systems tend to require very large parallel training corpora (Koehn and Knowles, 2017). Such corpora are not yet available for many language pairs.

The Indian subcontinent forms a *linguistic area* where languages from the Dravidian and Indo-Aryan families have been in **contact** for a long time leading to significant sharing of vocabulary and a convergence of linguistic features (Emeneau, 1956). Tamil is a major language from the Dravidian language family spoken in Southern India while Hindi is a widely spoken Indo-Aryan language. Kunchukuttan and Bhattacharyya (2020) estimate that lexical similarity between Hindi and Tamil to be around 27% in terms of character LCSR (Melamed, 1995), while multiple works have shown that language representations of Tamil and Hindi cluster in the same neighbourhood in a multilingual vector space (Kudugunta et al., 2019; Oncevay et al., 2020).

While English-Tamil parallel corpora is limited, more parallel corpora is available for English-Hindi. In this paper, we explore if English-Hindi can improve English-Tamil machine translation due to the similarities between Hindi and Tamil on account of contact relatedness. To this end, we train multilingual NMT models for English-Hindi and English Tamil (and vice-versa). Previous work has explored whether high-resource languages can transfer knowledge to genetically-related low-resource languages (Nguyen and Chiang, 2017; Dabre et al., 2017). In contrast, we explore if **contact relatedness** can benefit low resource languages. We further explore if reducing the divergence between Tamil and Hindi data by representing them in the same script is beneficial. In addition, we explored target agreement models, tagged and noisy back-translation in our submission.

2 Neural Machine Translation

Given a bilingual sentence pair (x, y), an NMT model learns its parameters θ by maximizing the log-likelihood $P(y|x;\theta)$, which is usually decomposed into the product of the conditional probability of each target word: $P(y|x;\theta) = \prod_{t=1}^{m} P_\theta(y_t|y_1, y_2, .., y_{t-1}, x;\theta)$, where m is the length of sentence y.

An encoder-decoder framework (Bahdanau et al., 2015; Luong et al., 2015; Gehring et al., 2017; Vaswani et al., 2017) is usually adopted to model the conditional probability $P(y|x;\theta)$. The encoder maps the input sentence x into a set of hidden rep-

Proceedings of the 5th Conference on Machine Translation (WMT), pages 202–206
Online, November 19–20, 2020.

resentations h, and the decoder generates the target token y_t at position t using the previously generated target tokens $y_{<t}$ and the source representations h. Both the encoder and decoder can be implemented by different structure of neural models, such as RNN (LSTM/GRU) (Bahdanau et al., 2015; Luong et al., 2015), CNN (Gehring et al., 2017) and self-attention (Vaswani et al., 2017). Besides the basic component of the encoder and decoder, a source-target attention mechanism (Bahdanau et al., 2015) is usually adopted to selectively focus on the source representations when generating a target token.

The Transformer (Vaswani et al., 2017) model is the state-of-the-art NMT model relying completely on self-attention mechanism to compute representations of its input and output without using recurrent neural networks (RNN) or convolutional neural networks (CNN). In this work, we use the Transformer architecture in all of our NMT models. We use smaller capacity networks compared to *Transformer-base*, given the smaller size of the parallel data.

3 Multilingual Learning for NMT

The objective of multilingual learning for NMT is to construct a single model for translating to and from multiple languages. Multilingual models can help improve performance of low-resource languages by transferring from high-resource related languages they are trained jointly with. Firat et al. (2017) introduced a many-to-many system, which still relied upon separate encoders and decoders for each language along with a shared attention mechanism. In contrast, Johnson et al. (2017) introduced a "language flag"-based approach that shares the attention mechanism and a single encoder-decoder network to enable multilingual models. A language flag or token is part to the input sequence to indicate which direction to translate to. The decoder learns to generate the target given this input. This approach has been shown to be simple and effective and we use this in our multilingual models. As mentioned earlier, we train a joint Hindi,Tamil to English model as well as a joint English to Hindi,Tamil model. Our hypothesis is that the contact relatedness between Hindi and Tamil will help transfer knowledge from Hindi to Tamil effectively.

Tamil and Hindi use different scripts. However, it is possible to map almost all Devanagari (the script used for Hindi) characters to Tamil characters. This mapping is deterministic but lossy since the Tamil character set is smaller than the Devanagari character set. Such mapping will help to utilize the lexical similarity between the two languages directly. Hence, we convert all Hindi data to Tamil script during a pre-processing step. We also report results of our MultiNMT models without script conversion of Hindi to Tamil.

4 Backtranslation

Backtranslation (BT) (Sennrich et al., 2016a) is a widely used data augmentation method where the reverse direction is used to translate sentences from target-side monolingual data into the source language. This synthetic parallel data is combined with the actual parallel data to re-train the model leading to better language modelling on the target-side, regularization and target domain adaptation. Backtranslation is particularly useful for low-resource languages. We use backtranslation to augment our multilingual models. The backtranslation data is generated by multilingual models in the reverse direction, hence some implicit multilingual transfer is incorporated in the backtranslated data also.

4.1 Noisy and Tagged Backtranslation

Backtranslation typically uses beam search (Sennrich et al., 2016a) or just greedy search (Lample et al., 2018a,b) to generate synthetic source sentences. Both are approximate algorithms to identify the maximum a-posteriori (MAP) output, i.e. the sentence with the largest estimated probability given an input. Beam is generally successful in finding high probability outputs (Ott et al., 2018). However, MAP prediction can lead to less rich translations since it always favors the most likely alternative in case of ambiguity. Edunov et al. (2018) argue that this is also problematic for a data augmentation scheme such as backtranslation. Beam and greedy search focus on the head of the model distribution which results in very regular synthetic source sentences that do not properly cover the true data distribution. Following the approach proposed by Edunov et al. (2018), we apply noising to the beam search outputs. In particular, we transform source sentences with three types of noise: deleting words with probability 0.1, replacing words by a filler token with probability 0.1, and swapping words which is implemented as a random permutation over the tokens, drawn from the uniform distribution but restricted to swapping words no

further than three positions apart.

Caswell et al. (2019) showed that main purpose of the synthetic noise is not to diversify the source but simply to indicate that the given source is synthetic. They proposed to prepend the input sequences of the synthetic data with a reserved token like <BT> to indicate that the given source is synthetic. In this paper, we experiment with both Noisy BT and Tagged BT.

5 Target Agreement

Due to the autoregressive structure, current NMT systems usually suffer from the so-called exposure bias problem (Bengio et al., 2015): during inference, true previous target tokens are unavailable and replaced by tokens generated by the model itself, thus mistakes made early can mislead subsequent translation, yielding unsatisfactory translations with good prefixes but bad suffixes. Such an issue can become severe as sequence length increases. Zhang et al. (2019) showed that the impact of this can be reduced by augmenting the training data with synthetic targets generated by a left-to-right (L2R) and a right-to-left (R2L) translation model. The directionality of the synthetic targets ensures that decoder input distribution becomes noisier (as happens at runtime) along one side of the target. The augmented data thus serves to reduce the divergence in the decoder input distribution. This is especially relevant to low-resource language scenarios where the model is not as robust to the decoder input distribution.

6 Experimental Settings

6.1 Dataset

We train our models only on the parallel data provided for the task (see Table 1 for dataset details). For backtraslation, we randomly selected 10M sentences from the newscrawl 2019 English monolingual corpora. For Tamil monolingual corpora, used the entire newscrawl corpus (0.7M), Wikipedia corpus and part of the CommonCrawl data made available for a consolidated corpus of 10M sentences. We use IIT-Bombay Hindi-English parallel corpora v2.0 (Kunchukuttan et al., 2018) containing 1.5M parallel sentences to build our multilingual models. We used UFAL's Tamil-English dev set containing 1,000 parallel sentences for tuning our models.

Dataset	# of Sentences
Wikititles	102,146
Wikimatrix	52,669
PMIndia	39,526
Tanzil (Koran)	93,540
NLPC_UOM	8,945
PIB (CVIT@IIITH)	60,836
MKB (CVIT@IIITH)	5,744
UFAL	166,871
Total	530,277

Table 1: Tamil-English parallel corpus statistics.

6.2 Data Processing

We use the Moses (Koehn et al., 2007) toolkit[1] for lowercasing, tokenization and cleaning the English side of the data. Both Tamil and Hindi data are first normalized and then tokenized. The Hindi data is mapped to Tamil script. We use the Indic NLP library[2] (Kunchukuttan, 2020) for text processing of the Indic languages. We remove all sentences of length greater than 80 words from our training corpus. In all cases, we use BPE subword segmentation (Sennrich et al., 2016b) with 32k merge operations. In case of mulitlingual models, we learn the BPE vocabulary jointly on the Hindi and Tamil data.

6.3 Training Details

For all of our experiments, we use the fairseq (Ott et al., 2019) toolkit[3]. We use the Transformer model with 4 layers in both the encoder and decoder, each with 512 hidden units. The word embedding size is set to 512 and 8 attention heads are used. The training is done in batches of maximum 2048 tokens at a time with dropout set to 0.2. We use the Adam (Kingma and Ba, 2015) optimizer to optimize model parameters with $\beta_1 = 0.9$, $\beta_2 = 0.98$ and $\epsilon = 1e - 9$ and we use the same learning rate schedule as Vaswani et al. (2017). We validate the model after each epoch via label smoothed cross entropy loss and perplexity on the development set. We train all our NMT models till convergence where convergence is determined by label smoothed cross entropy loss on the development set. After translation at the test time, we rejoin the translated BPE segments. Finally,

[1] https://github.com/moses-smt/mosesdecoder
[2] https://anoopkunchukuttan.github.io/indic_nlp_library/
[3] https://github.com/pytorch/fairseq

we evaluate the accuracy of our translation models using SacreBLEU (Post, 2018).

7 Results and Discussion

We report the SacreBLEU scores on the dev sets and test sets provided in the WMT20 News translation task for both the language directions: Tamil→English (Table 2) and English→Tamil (Table 3). We experimented with Multilingual (MultiNMT), Backtranslation (BT), Noisy Backtranslation (noisyBT) and Tagged Backtranslation (taggedBT) and Target Agreement (TA) models.

We observe that our multilingual models outperform the baseline bilingual models by significant margins. On the newstest2020 set, we see an improve of 2.9 and 1.5 BLEU points respectively in the Tamil→English and English→Tamil directions respectively. Note that the gains translating into multiple targets is lower. However, when backtranslated data is added we observe an improvement of 2.3 BLEU points in the en→ta quality. Note that the backtranslation data was generated via the multilingual ta→en model, hence there is an implicit benefit from multilinguality when using backtranslation. Backtranslation also provides a good improvement in the en→ta. We see that representing Indian language data in the same script was very beneficial for ta→en translation, while it did not help in the other direction. Having disjoint vocabularies during generation possibly helps the model learn distinct language models for Hindi and Tamil.

Our results indicate that Target Agreement and Noisy and Tagged Backtranslation schemes are not helpful in increasing the translation performance of the NMT models for the language pairs of our interest and requires more investigation on low resource language translation tasks. Further analysis is needed to understand why backtranslation variants and target agreement did not show improvements in our setting.

System	newsdev2020	newstest2020
Transformer baseline	10.4	10.0

MultiNMT+BT+TA	19.1	14.2

Table 2: Tamil→English (Ta-En) experiment results.

System	newsdev2020	newstest2020
Transformer baseline	6.1	3.5
MultiNMT (no script conversion)	7.5	4.9
MultiNMT	7.4	5.0
MultiNMT+BT	**11.5**	**7.3**
MultiNMT+BT+TA	11.3	7.3

Table 3: English→Tamil (En-Ta) experiment results.

8 Conclusion

We believe contact relatedness can be utilized in the multilingual NMT framework for improving low-resource language translation. Our initial results confirm this for English-Tamil translation aided by English-Hindi data. In addition, we show, that the popular data augmentation methods like backtranslation further helps in increasing the translation performance of Multilingual NMT models.

The AFRL WMT20 News-Translation Systems

Jeremy Gwinnup and **Timothy Anderson**
Air Force Research Laboratory
{jeremy.gwinnup.1, timothy.anderson.20}@us.af.mil

Abstract

This report summarizes the Air Force Research Laboratory (AFRL) machine translation (MT) systems submitted to the news-translation task as part of the 2020 Conference on Machine Translation (WMT20) evaluation campaign. This year we largely repurpose strategies from previous years' efforts with larger datasets and also train models with precomputed word alignments under various settings in an effort to improve translation quality.

1 Introduction

As part of the 2020 Conference on Machine Translation (wmt, 2020) news-translation shared task, the AFRL human language technology team participated in the Russian–English portion of the competition. We largely employed our strategies from last year including language-based filtering of training corpora with fastText (Joulin et al., 2016b,a), employing transformer-based (Vaswani et al., 2017) translation models and once again utlitizing system combination to fuse outputs from OpenNMT (Klein et al., 2018), Marian (Junczys-Dowmunt et al., 2018) and Moses (Koehn et al., 2007) systems. We also examine the effects of training Marian models with externally generated word alignments as described in (Alkhouli et al., 2018).

2 Data processing

For purposes of training our systems, we use the following parallel corpora: Commoncrawl (Smith et al., 2013), Yandex[1], UN v1.0 (Ziemski et al., 2016), Paracrawl[2](Esplà et al., 2019), Wikimatrix (Schwenk et al., 2019), and backtranslated data from our WMT17 system (Gwinnup et al., 2017) as well as Edinburgh's WMT17 system (Sennrich et al., 2017) yielding a raw corpus of over 76.3 million lines.

We prepare training corpora in a similar manner described in (Gwinnup et al., 2018), however this year, we utilize SentencePiece (Kudo and Richardson, 2018) with a 46k-entry vocabulary[3] for processing subword units instead of byte-pair encoding (BPE) (Sennrich et al., 2016).

2.1 Language-ID based data filtering

As with last year's efforts, we again employ fastText (Joulin et al., 2016b,a) to filter the various parallel corpora with a utility examining the source and target sentence pairs, discarding pairs where either (or both) sentence in the pair falls below a threshold score of 0.8. We wished to explore different threshold values, but our team did not have access to the majority of our computational assets due to the COVID-19 pandemic, limiting the bandwidth available for experiments.

We show the results of language-ID based filtering in Table 1. On average, 76.79% of the original training data is retained, with our WMT17 backtranslated data retaining the largest percentage of lines at 93.22% - this is interesting since that data originated as English and was translated to Russian with a very shallow Amun (Hoang et al., 2018) model. Again, Paracrawl yielded the least percentage of retained lines at 42.90%, but is understandable due to the "raw" nature of this particular release.

2.2 Guided Alignment

Inspired by the results in (Alkhouli et al., 2018), we've examined effects of using precomputed word alignments as a guide during training; Marian has a facility to train in this manner. Alignments were generated using Fastalign (Dyer et al., 2013)

paracrawl	12,061,155	5,173,675	42.90%
wikimatrix	5,203,872	4,287,881	82.40%
wmt17-afrl-bt	8,921,942	8,317,107	93.22%
wmt17-uedin-bt	36,772,770	29,074,022	79.06%
Total	76,367,946	58,567,425	76.69%

Table 1: Results of language-id based Russian–English corpus filtering with threshold of 0.8

on both "plain" and SentencePiece-processed data; MGIZA (Gao and Vogel, 2008) alignments were only generated for the word-based data. In order to generate these alignments, the language-id filtered corpus described in the previous section was further processed using Moses's clean-corpus-n-ratio script as well as escaping various characters and entities (such as ' replaced with &) yielding a final corpus of 49,866,140 lines. Additionally, a 46k entry SentencePiece model is built on this corpus with user-defined vocabularies for the tokens escaped during processing.

We use a Procrustes alignment projection script[4] to effectively map alignments generated on whole word tokens to the equivalent series of subword tokens in the SentencePiece processed data. Comparisons are drawn between Marian models trained on these various conditions in Section 3.2.

3 Machine Translation Systems

This year, we focused system-building efforts on the OpenNMT, Marian, and Moses toolkits. While most of our experimentation builds off of previous years' efforts, this year we examine the effects of "guided-alignment" training with the Marian toolkit in an attempt to improve translation quality.

3.1 Open-NMT

The OpenNMT system trained for this task used the the configuration for a large transformer network.

We used the following network hyperparameters:

- 1024 embedding size
- 4096 hidden units
- 12 layer encoder
- 12 layer decoder
- 16 transformer heads
- dropout 0.3
- attention dropout 0.1
- Tied embeddings for source, target and output layers
- Layer normalization
- Label smoothing
- Learning rate warm-up

The corpus was processed with SentencePiece using a model with a vocabulary size of 40K trained on the ru-en corpus. The network was trained for 10 epochs of this training data using a batch size of 1562, with an effective batch size of 24,992 using the lazy Adam (Kingma and Ba, 2015) optimizer. The final system was an average of the last 8 checkpoints of the training. Checkpoints were saved every 5000 steps. The system was then tuned with one epoch of newstest data from years 2014-2017.

3.2 Marian

Our Marian systems also utilize the transformer architecture. We use the WMT14 newstest2014 test set for validation during training and the following network hyperparameters:

- 2048 hidden units

[4] https://bitbucket.org/ndnlp/procrustes/src/master

- 6 layer encoder
- 6 layer decoder
- 8 transformer heads
- Tied embeddings for source, target and output layers
- Layer normalization
- Label smoothing
- Learning rate warm-up and cool-down

We first train a baseline system with the 58 million line corpus outlined in 2.1 and then train another baseline on the further-filtered 49 million line corpus outlined in 2.2. Using the word alignments generated earlier, we train systems utilizing alignments on subwords using fastalign (ga-spm-fastalign), alignments generated by projecting word-based fastalign alignments onto SentencePiece tokens (ga-procrusted-fastalign), and word-based MGIZA alignments onto SentencePiece tokens (ga-procrustes-mgiza). Results for decoding newstest2014 for each of these models are shown in Table 2.

system name	newstest2014
full-corpus baseline	39.81
ga-baseline	34.17
ga-spm-fastalign	33.06
ga-procrustes-fastalign	33.49
ga-procrustes-mgiza	31.92

Table 2: Experimental results for both baseline and guided-alignment systems decoding WMT14 testset measured in cased, detokenized BLEU.

We see that the best performing system is the one trained on the larger corpus, which is not surprising. We also see that while none of the guided-alignment based approaches we tried scored higher than the baseline on the smaller guided-alignment corpus, using the fastalign projected alignments performs better than the fastalign subword-based alignments by approximately 0.4 BLEU. We did experience issues getting MGIZA to successfully run on the 49 million line corpus, which may suggest additional processing of the training corpus is necessary to generate "correct" alignments using that approach. However, this specific MGIZA run provided the word alignments used in the Moses system described in the next section. This suggests more careful examination may be necessary before drawing conclusions as to the efficacy of using guided alignments to the Marian training process.

3.3 Moses

As in previous years, we trained a phrase-based Moses (Koehn et al., 2007) system with the guided-alignment data outlined in Section 2.2 in order to provide diversity for system combination. This system employed a hierarchical reordering model (Galley and Manning, 2008) and 5-gram operation sequence model (Durrani et al., 2011). The 5-gram English language model was trained with KenLM (Heafield, 2011) on the constrained monolingual corpus from our WMT15 (Gwinnup et al., 2015) efforts. System weights were tuned with the Drem (Erdmann and Gwinnup, 2015) optimizer using the "Expected Corpus BLEU" (ECB) metric.

3.4 System Combination

Once again, Jane (Freitag et al., 2014) system combination was used to combine various systems, tuned on newstest2016. We were able to successfully combine variations of three and four input systems, with results discussed in the following section.

4 Experimental Results

Results of decoding our various MT systems on WMT test sets from 2014 through 2019 are shown in Table 3.

Marian-base is an ensemble of 5 transformer models trained with identical hyperparameters as outlined in Section 3.2, with the exception of the initial random seed and using the language-id filtered corpus described in Section 2.1. Individual model weights are trained via Drem (Erdmann and Gwinnup, 2015) as outlined in last year's system.

Marian-ga is an ensemble of the four guided-alignment models described in Section 3.2: ga-baseline, ga-spm-fastalign, ga-procrustes-fastalign and ga-procrustes-mgiza. Individual model weights are also trained with Drem.

Onmt-base is the baseline system described in Section 3.1 and onmt-tune is the system that was further finetuned on newstest 2014-2017; Scores on those test sets are not reported due to overfitting during the fine tuning process.

Variations of system combinations are also reported - again with the absence of onmt-tune due to concerns of overfitting as newstest2016 is the test set used for tuning the system combination process. Combinations of only two systems resulted in a segmentation fault during processing due to fragility in the combination process.

We entered System 8 as our primary submission due to its performance gain on newstest2019 in a general (non-finetuned) setting, with the intuition that this years test set would discuss similar topics or issues as last years, while the earlier sets may be dated. In contrast, we submit System 5 as an alternative due to finetuning adapting the model to the collection of recent test sets.

5 Conclusion

In addition to our "known-good" approaches with increased data to submit respectably-performing translation systems, we conducted several experiments with guided alignments. Although these systems didn't outperform our prior approaches, they did figure into our final system combination submitted to the evaluation.

The authors wish to thank David Chiang for his implementation of the Procrustes alignment-projection script. The authors would also like to thank Grant Erdmann, Emily Conway and Grace Smith for their assistance in human evaluation of MT output.

The Ubiqus English-Inuktitut System for WMT20

François Hernandez

Vincent Nguyen
Ubiqus, Paris, France
vnguyen@ubiqus.com

Abstract

This paper describes Ubiqus' submission to the WMT20 English-Inuktitut shared news translation task. Our main system, and only submission, is based on a multilingual approach, jointly training a Transformer model on several agglutinative languages. The English-Inuktitut translation task is challenging at every step, from data selection, preparation and tokenization to quality evaluation down the line. Difficulties emerge both because of the peculiarities of the Inuktitut language as well as the low-resource context.

1 Introduction

Ubiqus participated in the English to Inuktitut news translation task of WMT20. We performed a single submission, based on an unconstrained multilingual setup. The approach consists of jointly training a traditional Transformer (Vaswani et al., 2017) model on several agglutinative languages in order to benefit from them for the low-resource English-Inuktitut task (Aharoni et al., 2019).

Though the dataset provided for the task is sizable, with more than a million segments, it's quite narrow domain-wise, as it comes from proceedings of the Nunavut Hansard. The task being translation of news, it's expected to be a much wider domain. For that purpose, we extended the task with datasets of other - linguistically near - languages, as well as in-house datasets introducing more diversity to the domain.

All experiments were performed with the OpenNMT (Klein et al., 2017) toolkit, with *Tokenizer* [1] for data preprocessing and *OpenNMT-py* [2] for model training and inference.

[1]https://github.com/OpenNMT/Tokenizer
[2]https://github.com/OpenNMT/OpenNMT-py

2 Data

2.1 Training corpora

Based on prior internal work on English-Inuktitut translation tasks as well as other low-resource tasks, we focused our experiments on multilingual setups. Inuktitut is an agglutinative language, with a lot of particularities. Some *Uralic languages* like Finnish and Estonian can be considered close to Inuktitut in some linguistic aspects.

Most of our experiments are *unconstrained* with regards to the original WMT task in three ways:

- some datasets are taken from previous WMT tasks (English-Finnish, English-Estonian);
- some datasets are not in the WMT scope (more recent ParaCrawl[3] versions);
- some datasets were built in-house at Ubiqus Labs.

Some Inuktitut resources can easily be found on the internet, mostly from official government of Nunavut websites and initiatives. We performed two sets of data retrieval: a first one based on parallel crawling of multilingual websites, and a second one based on manual retrieval of parallel documents (mostly in PDF format) which then were automatically aligned with a commercial tool. In prior experiments, we also built a set of parallel news articles. Articles were manually retrieved and aligned from both the *Inuktitut* [4] magazine, which provides parallel versions of all its content in English, French, Inuktitut and Inuinnaqtun, and the Nunatsiaq News[5] website, which provides part of its content in both Inuktitut and English. We decided not to include this last dataset because of

[3]https://paracrawl.eu
[4]https://www.itk.ca/category/inuktitut-magazine/
[5]https://nunatsiaq.com

Proceedings of the 5th Conference on Machine Translation (WMT), pages 213–217

its high proximity with the *newsdev2020* and *newstest2020* of the task.

A summary of all the datasets used in the experiments is available in Table 1.

2.2 Evaluation sets

During our experiments, we conducted evaluation of the trained models with the provided *newsdev2020-eniu* as well as the *dev*, *devtest* and *test* parts of the Hansard dataset split. The latter were deduplicated prior to evaluation.

As a big part of our experiments revolve around multilingual aspects, we also used *newstest2018-enfi* and *newstest2019-enfi* for English-Finnish, as well as *newstest2018-enet* for English-Estonian.

Finally, we also conducted some evaluation over the test part of our in-house dataset built from *Inuktitut* magazine.

2.3 Data selection and cleaning

Deduplication as well as a few steps of cleaning were applied to every dataset. This consists of removing segments where:

- average token length too short or too long;
- source is strictly equal to target;
- numbers do not match between source and target side;
- source to target character ratio is too extreme.

The difference between raw and selected dataset size is shown in Table 1. It is noticeable that this step is especially important for our in-house datasets, where automatically crawled and aligned data is particularly messy. Also, it seems the Nunavut Hansard dataset is quite clean but contains a lot of duplicates.

2.4 Preprocessing and Tokenization

We decided to work on romanized Inuktitut. This allows straightforward parameter and vocabulary sharing in a basic bilingual English-Inuktitut setup, as well as maximizing the potential benefits of parameter sharing in a multilingual setup. Hence, all the Inuktitut data was romanized prior to any other processing, and we only converted back our *newstest2020-eniu* inferred hypothesis for submission.

All experiments were conducted on data tokenized with a BPE (Sennrich et al., 2016b) model with 12,000 merge operations, learned on the concatenation of all datasets – both source and target – presented in Table 1 (without any particular sampling strategy). This leads to a final vocabulary size of approximately 14k tokens. The choice of a smaller number of BPE merge operations stems from the agglutinative aspect of the language, leading us to think that dividing long tokens into more subwords might be beneficial to learn and share more useful representations. This seems to be also the approach in the baseline system proposed in (Joanis et al., 2020).

3 Experiments

3.1 Mixing languages

The method used to train models on multiple languages relies on the dataset weighting mechanism which is implemented within OpenNMT-py (Klein et al., 2020). When building batches, $weight_A$ examples are sampled from dataset A, then $weight_B$ from dataset B, and so on. This allows to dynamically subsample or oversample any specific dataset or language pair when training.

In order to allow Many-to-Many translation in a single shared model, we need to prepend each source with a tag indicating the target language (Johnson et al., 2017).

3.2 Bilingual only

Since we do not have any internal resource to assess the Inuktitut output, we started some bilingual experiments into English. With the English-Inuktitut datasets only, we realized that even with a base Transformer, the model converged very quickly and gave similar results with several varying hyper parameters. Also, changing the sampling weight of each sub-dataset did not have much impact to the final results. Moreover, English to Inuktitut bilingual experiments gave very poor results on our internal test set based on the Inuktitut Magazine. We hypothesize that there was some kind of overfitting to the Hansard domain. This is why we decided to extend a multilingual set up with more "news" based data.

3.3 Multilingual

We trained a few systems in the following order:

- first, a bilingual (and bidirectional) English-Inuktitut system (base configuration Transformer) using the Nunavut dataset as well as our in-house Web and Documents datasets;

Dataset	Origin	Raw	Selected
Nunavut Hansard v3.0 (Joanis et al., 2020)	WMT EN-IU 2020 Task	2,550,682	737,375
⋆Europarl English-Finnish	WMT EN-FI 2019 Task	1,969,624	1,564,994
⋆Europarl English-Estonian	WMT EN-ET 2018 Task	651,236	566,815
⋆ParaCrawlv6 English-Finnish	ParaCrawl Project	4,286,642	4,207,262
⋆ParaCrawlv6 English-Estonian	ParaCrawl Project	1,785,161	1,755,013
⋆Public Documents	Ubiqus	102,567	66,159
⋆Public Websites	Ubiqus	2,035,594	31,025

Table 1: Characteristics of the datasets used in the experiments. Datasets marked with ⋆ are considered out of the constraints of the WMT English-Inuktitut task.

- next, we added the English-Finnish data;
- then, we added the English-Estonian data;
- finally, we increased the model size.

Results for these systems are summed up in Table 3. We notice that multilingual setups are truly multilingual, in the sense that they provide output in the correct language, even though the scores are not very competitive (approx. 30% below the best scores at the time of the corresponding WMT tasks).

We decided to retain the bigger model (medium Transformer) for the submission. Bigger multilingual models tend to be better with regards to human evaluation, probably because the tasks are better spread across the parameters. This can be a problem in case of overfitting, which does not seem to be the case here as the scores remain in the same range. Also, the bigger model seems to give marginally better results in the additional tasks (Finnish and Estonian), which leads us to think it will be more robust to new test sets.

The configuration used for the final submission is the following:

- **Corpora and weights**: shown in Table 2.
- **Tokenization**: 12,000 BPE merge operations, learned on the concatenation of all datasets.
- **Model**: Transformer Medium (12 $heads$, $d_{model} = 768$, $d_{ff} = 3072$), with Relative Position Representations (Shaw et al., 2018).
- **Training**: Trained with OpenNMT-py on 6 RTX 2080 Ti, using mixed precision. Initial batch size is around 50,000 tokens, final batch size around 200,000 tokens. Training was stopped at 100k steps. Averaging was done continuously through exponential moving average.
- **Inference**: Shown scores are obtained with beam search of size 5 and average length penalty.

4 Future work

Our experiments remain in a rather traditional Neural Machine Translation scope, with the only addition of multiple languages and dataset weighting. Several paths can be explored from this starting point, such as adding more data for the current languages in the setup, authentic or synthetic (e.g. via back-translation (Sennrich et al., 2016a)), or adding other languages that might share some common characteristics, like Hungarian for instance.

Some additional work could also be explored on the tokenization part. For simplicity, our first approach in this paper relies on a very simple shared BPE approach. But, some more sophisticated approaches, maybe language-specific or morphologically adapted (Micher, 2018), may be worth exploring.

Finally, some more novel approaches could be tried, like massive pre-training methods such as BART (Lewis et al., 2019). A similar experimental process could be followed, starting from only the core languages of the task (English and Inuktitut), then extending to other languages and observe the impact.

5 Conclusion

Working on a new, unknown, language is always challenging. Even more so when this language is quite distant from any language you're used to. Also, automated metrics are far from being perfect for such tasks, especially in the context of such a particular language as Inuktitut.

Particularly for this task, human evaluation is key. But, as data, it's quite a scarce resource for Inuktitut. More knowledge of the language would be of tremendous help to better grasp the limits or interesting leads of the various models. One workaround can be to work on the opposite direction (Inuktitut to English), but there is no guarantee the model would have similar behaviour for similar tricks. And, some knowledge about Inuktitut would still be needed to analyze model behavior based on source inputs.

Abstract

In this paper, we introduced our joint team SJTU-NICT 's participation in the WMT 2020 machine translation shared task. In this shared task, we participated in four translation directions of three language pairs: English-Chinese, English-Polish on supervised machine translation track, German-Upper Sorbian on low-resource and unsupervised machine translation tracks. Based on different conditions of language pairs, we have experimented with diverse neural machine translation (NMT) techniques: document-enhanced NMT, XLM pre-trained language model enhanced NMT, bidirectional translation as a pre-training, reference language based UNMT, data-dependent gaussian prior objective, and BT-BLEU collaborative filtering self-training. We also used the TF-IDF algorithm to filter the training set to obtain a domain more similar set with the test set for finetuning. In our submissions, the primary systems won the first place on English to Chinese, Polish to English, and German to Upper Sorbian translation directions.

1 Introduction

Our SJTU-NICT team participated in the WMT20 shared task, including supervised track, unsupervised, and low-resource track. During the participation, we placed our attention on Polish (PL) → English (EN) and English (EN) → Chinese (ZH) on the supervised track, while on the unsupervised and low-resource track, the German (DE) ↔ Upper Sorbian (HSB) both directions are focused.

Our baseline system in supervised track is based on the Transformer big architecture proposed by Vaswani et al. (2017), in which its open-source implementation version `Fairseq` (Ott et al., 2019) is adopted. In the unsupervised and low-resource track, we draw on the successful experience of the `XLM` framework (Conneau et al., 2019), and used the two-stage training mode of masked language modeling (MLM) pre-training + back-translation (BT) finetune to obtain a very strong baseline performance. `Marian` (Junczys-Dowmunt et al., 2018) toolkit is utilized for training the decoder in reranking using machine translation targets instead of common GPT-style language modeling targets.

In order to better play the role of WMT evaluation in polishing the methods proposed or improved by our team (He et al., 2018; Li et al., 2018; Zhang et al., 2018; Zhang and Zhao, 2018; Xiao et al., 2019; Zhou and Zhao, 2019; Li et al., 2019b; Luo and Zhao, 2020), we divided the three language pairs we participated in into three categories:

1. Traditional language pair with rich parallel corpus: EN-PL,
2. Language pair with document-level information: EN-ZH,
3. Language pair with no or low parallel resources: DE-HSB.

In the supervised PL→EN translation direction, we based on the XLM framework to pre-train a Polish language model using common crawl and news crawl monolingual data, and proposed the XLM enhanced NMT model inspired from the idea of incorporating BERT into NMT (Zhu et al., 2020). Besides, we trained a bidirectional translation model of EN-PL based on the parallel corpus and further finetuned it to the PL→EN

direction.

In the supervised EN→ZH translation with document information, we propose a document enhanced NMT model based on Longformer (Beltagy et al., 2020). The training of our proposed document enhanced NMT model is split into three stages. In the first stage, we pre-train the Longformer document encoder with MLM target on the document text in Wikipedia dumps, UN News, and News Commentary monolingual corpus. A conventional Transformer-big NMT model is trained in the second stage. In the final stage, the Longformer encoder and conventional Transformer big NMT model are used to initialize the full document-enhanced NMT model parameters, in which the Longformer encoder is adopted to extract representations for the document of an input sequence, and then the document representations are fused with each layer of the encoder and decoder of the NMT model through attention mechanisms.

In the unsupervised machine translation track on DE-HSB, we experimented with the reference language based UNMT (RUNMT) (Li et al., 2020b) framework we proposed recently. Under this framework, we choose English as the reference language, and use the Europarl parallel corpus of EN-DE to enhance the unsupervised machine translation between DE and HSB. Specifically, we adopted reference language translation (RAT), reference language back-translation (RABT), and cross-lingual back-translation (XBT) three training targets with the help of the cross-lingual agreement provided by the EN-DE parallel corpus to enhance the unsupervised translation performance.

Due to the introduction of more explicit supervision signals brought by parallel corpus in the low-resource machine translation track on DE-HSB, we discarded the use of the weaker agreement provided by the reference language, conducted joint training on the unsupervised back-translation and the supervised (forward-)translation directly, and introduced BT-BLEU based collaborative filtering technology for further self-training. In addition, inspired by our previous work (Sun et al., 2020b), we also use MLM and translation language modeling (TLM) to continue pre-training the model while machine translation training.

In addition, in all basic NMT models, we empower the training process with our proposed data-dependent gaussian prior objective (D2GPo) (Li et al., 2020a), so that the model can maintain the diversity of the output. When the main model training is finished, the TF-IDF algorithm is employed to filter the training set according to the input of the test set, a training subset whose domain is more similar to the test set is obtained, and then used to finetune the model for reducing the performance degradation caused by domain inconsistency. For the final submission, an ensemble of several different trained models outputs the n-best predictions, and used the decoder trained with `Marian` toolkit to performs reranking to get the final system output.

2 Methodology

2.1 XLM-enhanced NMT

Pre-trained language models such as ELMo (Peters et al., 2018), BERT (Devlin et al., 2019), XLM (Conneau et al., 2019), XLNet (Yang et al., 2019), ALBERT (Lan et al., 2019) etc. have recently demonstrated a very dominant effect on natural language processing tasks. Several works (Clinchant et al., 2019; Imamura and Sumita, 2019; Zhu et al., 2020) leveraged a pre-trained BERT model for improving NMT and found that BERT can bring significantly better results over the baseline.

Since BERT and other pre-trained language models are trained on large scale corpus beyond the data provided by the WMT20 organizers, the direct use of BERT will make the system submitted unconstrained. Using an XLM model, a variant of BERT, pre-trained from scratch on the monolingual data provided by the official to enhance our NMT model, is a good choice to keep the system constrained. Moreover, the XLM model has the advantages of simple training preprocessing, low requirement for training environment that no specialized hardware such as TPU is needed. Inspired by the *BERT-fused model* proposed by Zhu et al. (2020), we built a *XLM-enhanced model*, in which we utilize XLM context-aware representations to adaptively interact with all layers in the NMT model with attention mechanism, instead of serving it as input embeddings only.

In the *XLM-enhanced model*, XLM as an additional encoder and the original encoder of NMT constitute a dual-encoder structure, which is very similar to our previous work (Li et al., 2019a). The XLM-encoder attention and XLM-decoder attention are essentially the same with the

Representation Learning Frameworks (RLFs) we proposed: Source-side fusion RLF (SRLF), Target-side fusion RLF (TRLF), and both-side fusion RLF (BRLF, which is a combination of SRLF and TRLF). Specifically, in the SRLF, given a source language input x, a Pre-trained Language Modeling (PLM) encoder (like BERT, XLM) first encodes it into a context-aware representation:

$$H_P = \texttt{PLM}^k(x), \tag{1}$$

where H_P is the output of the k-th layer of the PLM encoder. As PLM and NMT models adopt different sub-word segmentation rules or algorithms and the addition of special tokens are different, the input sequence length of PLM and NMT encoders is inconsistent or cannot correspond in every position. Assuming that i represents the position of the input sequence of NMT encoder, the hidden state H_E^l after fusion with H_P in SRLF of the l-th layer is:

$$\begin{aligned} H_E^l = \frac{1}{2}(&\texttt{attn}_\texttt{S}(H_E^{l-1}, H_E^{l-1}, H_E^{l-1}) \\ &+\texttt{attn}_\texttt{P}(H_E^{l-1}, H_P, H_P)), \end{aligned} \tag{2}$$

where $\texttt{attn}_S$ is a multi-head self-attention layer and $\texttt{attn}_P$ is the multi-head attention layer. H_E will eventually be output from the last layer as the final representation.

In the TRLF framework, the dual-encoder provides two encoded outputs; the decoder will use both contexts at the same time. In the case of layer l in the decoder, we have

$$\begin{aligned} H_{DS}^l &= \texttt{attn}_\texttt{MS}(H_D^{l-1}, H_D^{l-1}, H_D^{l-1}), \\ H_D^l &= \frac{1}{2}(\texttt{attn}_\texttt{EC}(H_{DS}^l, H_E, H_E) \\ &\quad +\texttt{attn}_\texttt{PC}(H_{DS}^l, H_P, H_P)), \end{aligned} \tag{3}$$

where $\texttt{attn}_\texttt{MS}$ is the multi-head future-masked self-attention layer, $\texttt{attn}_\texttt{EC}$ and $\texttt{attn}_\texttt{PC}$ are independent multi-head attention layer for context query.

In the condition that SRLF framework is only used, the representation of PLM is only fused into the final representation H_E in the encoder side; then the decoder side continues to use the original decoding ways: $H_D^l = \texttt{attn}_\texttt{PC}(\texttt{H}_\texttt{DS}^\texttt{l}, \texttt{H}_\texttt{E}, \texttt{H}_\texttt{E})$. While the the TRLF framework is only adopted, the output of NMT encoder is $H_E = \texttt{attn}_\texttt{S}(\texttt{H}_\texttt{E}^{\texttt{l}-1}, \texttt{H}_\texttt{E}^{\texttt{l}-1}, \texttt{H}_\texttt{E}^{\texttt{l}-1})$. A BRLF framework is a combination of these two frameworks.

Moreover, in the training of the RLFs, a same drop-net trick proposed by Zhu et al. (2020) is adopted to ensure that the features output by PLM and the conventional encoder are fully utilized. In this method, the interval of 0-1 is divided into three parts according to the pre-set drop-net ratio p_{net}, where $[0, \frac{p_{net}}{2})$ is the probability of attending to the final sum for the first `attn` in H_E^L and H_D^L, $[\frac{p_{net}}{2}, 1 - \frac{p_{net}}{2})$ is the probability for the whole H_E^L and H_D^L equation, $[1 - \frac{p_{net}}{2}, 1]$ is the probability for the second `attn` in in H_E^L and H_D^L.

2.2 Bidirectional NMT

Machine translation, in general, is unidirectional, that is, from the source language to the target language. The encoder-decoder framework for NMT has been shown effective in large data scenarios, and the more high-quality bilingual training data, the better performance the model tends to achieve. Recent works (Zoph et al., 2016; Kim et al., 2019) on translation transfer learning (Torrey and Shavlik, 2010; Pan and Yang, 2009) from rich-resource language pairs to low-resource language pairs demonstrate that translation has some universal nature in essence between different language pairs. As the source-to-target (S2T) forward translation and target-to-source (T2S) backward translation can be seen as two special language pairs in bilingual translation, it can make use of the translation universal nature to improve each other, i.e., dual learning (He et al., 2016). Based on this motivation, we developed a bidirectional NMT model, in which the S2T and T2S translation were trained and optimized jointly. Therefore, the training data was doubled to make better and full use of the costly bilingual corpus.

Given parallel corpus $\mathcal{C} = \{(x^{(n)}, y^{(n)})\}_{n=1}^N$, the bidirectional NMT model is trained in two phase. In the first *bidirectional translation as pre-training* phase, a joint training objective is used to jointly maximize the likelihood of both translation direction on the bilingual data:

$$\mathcal{L}(\theta_{parent}) = \sum_{n=1}^{N}(\log p(y^{(n)}|x^{(n)}) + \log p(x^{(n)}|y^{(n)})), \tag{4}$$

where θ_{parent} is the parameters of the model, namely *parent model*, obtained in this phase.

The second phase is *unidirectional translation fine-tuning*. Although there are commonalities in different translation directions, the differences are also very obvious. To further expose the model to the direction difference and improve the effect of unidirectional translation, we further finetune the

bidirectional pre-trained model on the bilingual data. Take S2T translation as an example; the model is optimized as follows:

$$\mathcal{L}(\theta_{S\to T}) = \sum_{n=1}^{N} \log p(y^{(n)}|x^{(n)}), \qquad (5)$$

where $\theta_{S\to T}$ is the parameters of *child model* which is initialized with θ_{parent}. Similarly, the T2S *child model* can also be obtained.

Due to the introduction of bidirectional translation in one model, follow the practice of Conneau and Lample (2019), shared subword vocabulary and shared encoder-decoder (source and target) embedding were employed to improves the alignment of embedding spaces across languages. In addition, since the encoder and decoder need to be able to handle two languages simultaneously, a language embedding was used to indicate the language being processed, so as to reduce confusion of the model.

2.3 Document-enhanced NMT

In spite of its success (Vaswani et al., 2017), sentence-level NMT has been based on strong independence and locality assumptions generally, in which the interrelations among these discourse (Jurafsky, 2000) elements were ignored. This results in that the translations may be perfect at the sentence-level but lack crucial properties of the text, hindering understanding (Maruf et al., 2019). To help to resolve ambiguities and inconsistencies in translations, some MT pioneers (Bar-Hillel, 1960; Xiong et al., 2013; Sennrich, 2018) exploit the underlying discourse structure information of a text to address this issue, while others (Bawden et al., 2018; Voita et al., 2018; Jean and Cho, 2019; Wang et al., 2019; Scherrer et al., 2019) extend the translation units with the context or use an additional context encoder and attention. It is worth noting that the essence of the document-level NMT claimed with additional context and attention is still sentence-level MT, whose translation is still output sentence by sentence. We named it as document-enhanced NMT more precisely.

Due to computational efficiency and tractability concerns, the document-enhanced NMT models mostly used document embedding, document topic information, and limited past or future context sentences, etc., rather than the truly whole document information. Recently, with the increase in computational power available to us and the well-designed neural network structures (Dai et al., 2019; Kitaev et al., 2019; Beltagy et al., 2020) for long sequence encoding, we are finally in a position to employ the whole document information for enhancing sentence-level NMT. In addition, we argue that since long sequences encoding is easier than decoding, truly whole document-level translation is still a long way off, since the bidirectional context is available in the encoder, but only the past is visible by the decoder.

Longformer To make the long documents processed with Transformer (Vaswani et al., 2017) architecture feasible or easier, a modified Transformer architecture named Longformer was proposed by Beltagy et al. (2020), in which the limitation for memory and computational requirements is addressed with a novel self-attention operation scales linearly with the sequence length.

In Longformer, the original full self-attention ($O(n^2)$ time and memory complexity) is sparsified to makes it efficient for longer sequences. There are three "attention patterns" for specifying pairs of input locations attending to one another.

- **Sliding Window** Self-attention is performed in a fixed-size window w and multiple stacked layers of such sliding windowed attention results in a large receptive field as analogs to CNNs.
- **Dilated Sliding Window** Inspired by the dilated CNNs (Oord et al., 2016), dilation gaps of size d is introduced to the window to further increase the receptive field without increasing computation.
- **Global Attention** Though the receptive field is enlarged by stacking multiple layers and dilation in sliding window and dilated sliding window attention patterns, some part of the long sequence has the requirement for keeping the full and global receptive field due to the downstream tasks, so global attention is introduced to make up this need.

In our document-enhanced NMT model, some heads in multi-head attention are set to use the sliding window pattern to focus on the local context which was revealed very important (Kovaleva et al., 2019), while others with dilation focus on longer context. Besides, as Longformer is incorporated into the NMT model, we perform

global attention on the position of `[CLS]` token in which the representation of the whole sequence (i.e., the document embedding) is generated. This makes the previous document-enhanced model with document embedding as a special case of ours. It is worth noting that since the sentence being translated is part of the document, setting its positions in the document to use global attention pattern will improve the performance; but to reduce the document computation and use cache for acceleration (not recalculate the document for each sentence), we only attend the `[CLS]` position globally.

In our document-enhanced model, the Longformer is first pre-trained with the masked language modeling objective on the monolingual document corpus. It is fixed throughout the NMT training to reduce the model parameters optimized in the training stage. Thus, Longformer can also be thought of as a pre-trained language model, as it provides a document context representation H_P for the NMT model, the integration of Longformer in *Document-enhanced NMT* is consistent with the XLM model in *XLM-enhanced NMT*.

2.4 Reference Language based UNMT

The rise of UNMT almost completely relieves the parallel corpus curse, though UNMT is still subject to unsatisfactory performance due to the vagueness of the clues available for its core back-translation training. Further enriching the idea of pivot translation by extending the use of parallel corpora beyond the source-target paradigm, we propose a new reference language-based framework for UNMT, RUNMT, in which the reference language only shares a parallel corpus with the source, but this corpus still indicates a signal clear enough to help the reconstruction training of UNMT through a proposed reference agreement mechanism.

Specifically, we proposed three kinds of reference agreement utilization approaches in (Li et al., 2020b): reference agreement translation (RAT), reference agreement back-translation (RABT), and cross-lingual back-translation (XBT).

RAT RAT utilizes the principle for translating paired sentences into the target language $\mathcal{T}$ of the source $\mathcal{S}$ and reference $\mathcal{R}$ language. Since the input the parallel, the both translation outputs should be the same. Given a parallel sentence pair $\langle s, r\rangle$ between language $\mathcal{S}$ and $\mathcal{R}$, we would ideally have $\mathbb{P}(\cdot|s;\theta_{\mathcal{S}\to\mathcal{T}}) = \mathbb{P}(\cdot|r;\theta_{\mathcal{R}\to\mathcal{T}})$, where $\theta_{\mathcal{S}\to\mathcal{T}}$ and $\theta_{\mathcal{R}\to\mathcal{T}}$ represent $\mathcal{S}\to\mathcal{T}$ and $\mathcal{R}\to\mathcal{T}$ translation models respectively. However, as the two models are trained on different data, the agreement may be corrupted. Therefore, we combine the two models to obtain the agreed-upon translation output $\tilde{t}_a$:

$$\tilde{t}_a \sim \mathbb{P}(\cdot|s,r;\theta_{\mathcal{S}\to\mathcal{T}},\theta_{\mathcal{R}\to\mathcal{T}}), \tag{6}$$

where $\mathbb{P}(\cdot|s,r;\theta_{\mathcal{S}\to\mathcal{T}},\theta_{\mathcal{R}\to\mathcal{T}})$ is

$$\prod_{i=1}^{J}[\frac{1}{2}(\mathbb{P}(\cdot|s,\tilde{t}_{<i};\theta_{\mathcal{S}\to\mathcal{T}}) + \mathbb{P}(\cdot|r,\tilde{t}_{<i};\theta_{\mathcal{R}\to\mathcal{T}}))], \tag{7}$$

$\tilde{t}_{<i}$ indicates the decoded tokens before the i-the generation step.

Finally, two synthetic sentence pairs $\langle s,\tilde{t}_a\rangle$ and $\langle r,\tilde{t}_a\rangle$ are used to train the models $\mathcal{S}\to\mathcal{T}$ and $\mathcal{R}\to\mathcal{T}$. Since the silver learning target is optimized, the smoothed cross-entropy loss $\mathcal{L}_\epsilon$ is used instead of the ordinary cross-entropy loss $\mathcal{L}$. The learning objective for RAT can be written as:

$$\mathcal{L}_{\mathbf{RAT}}(\mathcal{S},\mathcal{T},\mathcal{R}) = \mathcal{L}_\epsilon(\theta_{\mathcal{S}\to\mathcal{T}}) + \mathcal{L}_\epsilon(\theta_{\mathcal{R}\to\mathcal{T}}), \tag{8}$$

RABT With the regularized pseudo-parallel sentences in RAT, we not only train the $\mathcal{S}\to\mathcal{T}$ and $\mathcal{R}\to\mathcal{T}$ forward-translation models (as the generation direction is the same as the training direction), but also train the BT models, i.e., $\mathcal{T}\to\mathcal{S}$ and $\mathcal{T}\to\mathcal{R}$. The learning objective of RABT can be described as:

$$\mathcal{L}_{\mathbf{RABT}}(\mathcal{S},\mathcal{T},\mathcal{R}) = \mathcal{L}(\theta_{\mathcal{T}\to\mathcal{S}}) + \mathcal{L}(\theta_{\mathcal{T}\to\mathcal{R}}). \tag{9}$$

XBT The parallel corpus between languages $\mathcal{S}$ and $\mathcal{R}$ can not only bring agreement in the translations of the same target language $\mathcal{T}$, but also cross-lingual agreement, that is, using the target language as the bridge to form pivot translation (Wu and Wang, 2007; Utiyama and Isahara, 2007; Paul et al., 2009) patterns: $\mathcal{S}\to\mathcal{T}\to\mathcal{R}$ and $\mathcal{R}\to\mathcal{T}\to\mathcal{S}$. In XBT, paired sentences s and r are translated to language $\mathcal{T}$: $\tilde{t}_s$ and $\tilde{t}_r$, and forms two new pseudo-parallel pairs: $\langle\tilde{t}_s,r\rangle$ and $\langle\tilde{t}_r,s\rangle$, which promote the training of translation $\mathcal{T}\to\mathcal{R}$ and $\mathcal{T}\to\mathcal{S}$. The objective function of XBT is:

$$\mathcal{L}_{\mathbf{XBT}}(\mathcal{S},\mathcal{T},\mathcal{R}) = \mathcal{L}(\theta_{\mathcal{T}\to\mathcal{R}}) + \mathcal{L}(\theta_{\mathcal{T}\to\mathcal{S}}), \tag{10}$$

2.5 CFST: Collaborative Filter for Self-Training with BT-BLEU

Self-training, proposed by Scudder (1965), is a semi-supervised approach that utilizes unannotated

Algorithm 1 Classic Self-training

1: Train a base NMT/UNMT model $f_{\theta_{S\to T}}$ on $\mathcal{C}$
2: **repeat**
3: Apply $f_{\theta_{S\to T}}$ to the unlabeled instances $\mathcal{U}$
4: Select a subset $\mathcal{Q} \subset \{(x, f_{\theta_{S\to T}}(x))|x \in \mathcal{U}\}$
5: Update model $f_{\theta_{S\to T}}$ on $\mathcal{Q}$ with self-training objective and $\mathcal{C}$ with original objective
6: **until** convergence or maximum iterations are reached

data to create better models. Recently, self-training has been successfully applied to both NMT and UNMT fields (He et al., 2019; Sun et al., 2020a), especially for the unbalanced low-resource training data scenarios.

Formally, in self-training strategy for machine translation, a parallel dataset $\mathcal{C} = \{(x^{(n)}, y^{(n)})\}_{n=1}^{N}$ in NMT and a unpaired monolingual dataset $\mathcal{D} = \{x^{(m)}\}_{m=1}^{M} \cup \{y^{(n)}\}_{n=1}^{N}$ in UNMT is used to train the initial model. Then, a subset of pseudo parallel data is incorporated to update the model with a pseudo-supervised NMT (PNMT) objective (including forward translation and backward translation) for both NMT and UNMT as shown in Algorithm 1. In NMT, a large unlabeled dataset $\mathcal{U} = \{x^{(j)}\}_{j=1}^{L}$ is used for the synthesis of pseudo-parallel corpora. While in UNMT, since the model is trained with back-translation on unpaired monolingual data, the pseudo-parallel corpora is synthesized by the monolingual data, i.e., $\mathcal{U} = \{x^{(m)}\}_{m=1}^{M}$.

Considering the translation quality can't effectively be evaluated across languages in machine translation with only the monolingual data, therefore the selection of the subset $\mathcal{Q}$, is one of the key factors for self-training. It is usually selected based on some confidence scores (e.g. log probability or perplexity, PPL) (Yarowsky, 1995), but it is also possible for S to be the whole pseudo parallel data (Zhu and Goldberg, 2009). In the backward translation based on the pseudo-parallel data, the DAE method widely used in UNMT can alleviate the impact of the noise resulted from the synthesized sentences on model training, since the synthesized sentences are only used as input. However, in the forward translation training, the quality of noisy targets will directly affect the success of the model training. Therefore, the selection of synthetic parallel corpus becomes particularly critical.

Algorithm 2 BT-BLEU based Collaborative Filter

1: Split $\mathcal{U}$ equally into two subsets $\mathcal{U}_1 = \{x^{(j)}\}_{j=1}^{L/2}$ and $\mathcal{U}_2 = \{x^{(j)}\}_{j=L/2+1}^{L}$
2: Apply $f_{\theta_{S\to T}}$ to the unlabeled instances $\mathcal{U}_1$ and $\mathcal{U}_2$
3: Train two backward translation models $f^{(1)}_{\theta_{T\to S}}$ with $\{(f_{\theta_{S\to T}}(x), x)|x \in \mathcal{U}_1\}$ and $f^{(2)}_{\theta_{T\to S}}$ with $\{(f_{\theta_{S\to T}}(x), x)|x \in \mathcal{U}_2\}$ respectively
4: Translate $\{f_{\theta_{S\to T}}(x)|x \in \mathcal{U}_2\}$ with model $f^{(1)}_{\theta_{T\to S}}$, while $\{f_{\theta_{S\to T}}(x)|x \in \mathcal{U}_1\}$ with model $f^{(2)}_{\theta_{T\to S}}$
5: Calculate BT-BLEU $\mathcal{B}$ for two subsets: $\textbf{BLEU}(f^{(2)}_{\theta_{T\to S}}(f_{\theta_{S\to T}}(x)), x), \forall x \in \mathcal{U}_1$ and $\textbf{BLEU}(f^{(1)}_{\theta_{T\to S}}(f_{\theta_{S\to T}}(x)), x), \forall x \in \mathcal{U}_2$
6: $\mathcal{Q} = \{(x, f_{\theta_{S\to T}}(x))|x \in \mathcal{U}_1, \mathcal{B} > \gamma\} \cup \{(x, f_{\theta_{S\to T}}(x))|x \in \mathcal{U}_2, \mathcal{B} > \gamma\}$

We propose a collaborative filtering algorithm based on BT-BLEU to select high quality pseudo-parallel pairs, as shown in Algorithm 2. The BT-BLEU, as defined in (Li et al., 2020b), is a BLEU of $\boldsymbol{x} \in \mathcal{S}$ and $\tilde{\boldsymbol{x}}$ generated in the $\mathcal{S} \to \mathcal{T} \to \mathcal{S}$ back-translation process. As long as the model of $\mathcal{T} \to \mathcal{S}$ is fixed and the preference for translation of certain sentences is reduced as much as possible, BT-BLEU can reflect the translation quality of $\mathcal{S} \to \mathcal{T}$ to some extent, because of the necessary but insufficient condition that only the better the translation of $\mathcal{S} \to \mathcal{T}$ is, the better the translation of $\mathcal{T} \to \mathcal{S}$ can be.

To achieve the goal of reducing translation preferences, we split the pseudo parallel set into two subsets, ensure no overlap between two subsets. The model trained on subset 1 is used for back-translation on the subset 2, while the model on subset 2 back-translate the subset 1. This collaborative translation process enables the two models not to see the sentences to be translated, which guarantees the translation not relies on tricks. Additionally, we found that the sentences in different lengths have different difficulties for back-translation; we further divide the sentences into different bags according to their lengths and use different BT-BLEU threshold γ for filtering.

2.6 TF-IDF Finetune

NMT has been prominent in many machine translation tasks. However, in some domain-specific tasks, only the corpora from similar

Table 1: PL→EN performance (sacreBLEU and chrF score) for different models.

domains can improve translation performance. If a trained NMT model is evaluated on a domain mismatch corpus, the translation performance may even degrade. Therefore, domain adaptation techniques are essential to solve the NMT domain problem. It is a very common domain adaptation approach to further finetune the translation model trained on the domain-mixed corpus by using data that is the same or similar to the test set in domain. Therefore, we need to select sentences that are as close to the input domain as possible in the domain-mixed training set.

We argue that low-frequency words contain more domain information than high-frequency words, since low-frequency words are mostly domain-specific nouns, etc., which may indicate the topic directly. Therefore, we adopt the TF-IDF algorithm to search and filter on the whole training set. In fact, the improved version of TF-IDF algorithm, BM25 (Robertson and Zaragoza, 2009), is employed to calculate the sentence similarity. BM25 is based on probabilistic information retrieval theory, whose score for a term q to a sequence Q is:

$$s(Q,q) = \frac{\text{IDF} * ((k+1) * \text{TF})}{(k * (1.0 - b + b * \frac{L_Q}{L_{\text{avg}}}) + \text{TF})}, \quad (11)$$

where IDF is the Inverse Document Frequency for term q appears in the whole corpus, TF is the Term Frequency for q in D, L_Q represents the sequence length, L_{avg} is the average length of corpus D, k and b is the adjustable parameters.

With this scorer, every sequence will obtain a BM25 vector on the terms of the corpus:

$$V = [s(Q,t), \quad \forall t \in D_{\text{terms}}], \quad (12)$$

where D_{terms} indicates the all terms set in corpus D. We calculate the cosine similarity as final scores between the query and every source sentence in corpus, and ranked on the scores to get the top-K pairs (K=1000 in our experiments) as the sub-training set for finetuning.

3 Data Preprocessing and Model Setup

Before model training, we preprocessed the data uniformly and customized the processing according to the requirements of each model. We normalized punctuation, remove non-printing characters, and tokenize all data with the Moses tokenizer (Koehn et al., 2007) except for the Chinese. For Chinese, we removed the segmentation space in some training data and then use PKUSeg (Luo et al., 2019) toolkit to cut all Chinese sentences, so as to obtain unified word segmentation annotations. We use joint byte pair encodings (BPE) with 40K split operations for subword segmentation (Sennrich et al., 2016).

In *XLM-enhanced NMT* and *Document-enhanced NMT*, we first train a basic NMT (Transformer big) model on the sentence-level data until convergence, then initialize the encoder and decoder of the *XLM-enhanced NMT* and *Document-enhanced NMT* full model with the obtained model. The PLM-encoder attention $\texttt{attn}_{\texttt{P}}$ and PLM-decoder attention $\texttt{attn}_{\texttt{PC}}$ are randomly initialized.

EN-PL On the language pair EN-PL, we explored performance in two training data settings. The first is *base data*, including Europarl v10, Tilde Rapid corpus, and WikiMatrix bitext data, whose raw data is on the sentence-level. In the second setting *base data + paracrawl*, we converted the paragraph-level alignment data in Paracrawl to sentence-level alignment and incorporated it with the *base data*. In the conversion process, we adopted the method and program proposed by (Gale and Church, 1993) for aligning sentences based on a simple statistical model of character lengths, which uses the fact that longer sentences in one language tend to be translated into longer sentences in the other language, and that shorter sentences tend to be translated into shorter

Table 2: EN→ZH performance (charBLEU and chrF score) for different models.

sentences. A probabilistic score is assigned to each proposed correspondence of sentences, based on the scaled difference of lengths of the two sentences (in characters) and the variance of this difference. This probabilistic score is used in a dynamic programming framework to find the maximum likelihood alignment of sentences.

For the Polish pre-trained XLM language model, we used all NewsCrawl monolingual data and some CommonCrawl monolingual data. Since the CommonCrawl data is very large and noisy and can potentially decrease the performance of LM if it is used in its raw form. We apply language identification filtering (`langid`; Lui and Baldwin (2012)), keeping sentences with correct languages. In order to filter out the sentences shorter than 5 words or longer than 150 words more precisely, we re-split sentences using Spacy (Honnibal and Montani, 2017) toolkit.

EN-ZH In EN-ZH, the pre-training of Longformer as a document encoder is unique. As described in (Beltagy et al., 2020), the Longformer needs a large number of gradient updates to learn the local context first; before learning to utilize longer context. In the first phase of the staged training procedure, an initial RoBERTa (Liu et al., 2019) model implemented in Fairseq (Ott et al., 2019) repository was trained on the sentence-level text available. In each subsequent phase, we trained the model on the paragraph text, doubled the window size and the sequence length, and halve the learning rate. For the paragraph text, the Wikidumps and NewsCommentary v15 have document intervals and can be used directly, while UN v1.0 has no document intervals but the sentence order is not interrupted. Therefore, we use the BERT Next Sentence Prediction (NSP) classification model provided by Google for document interval prediction to recover the documents.

DE-HSB In RUNMT on EN-DE-HSB, Europarl v10 EN-DE parallel corpus is used for EN-DE NMT and RAT/RABT/XBT training[1]. Additionally, the BPE size increases to 50K for three languages. In CFST, the filtering threshold of BT-BTBLEU is set to $\gamma = 50.0$.

4 Results and Analysis

Results and ablations for PL→EN[2] are shown in Table 1, EN→ZH in Table 2, unsupervised DE↔HSB in Table 3 and low-resource DE↔HSB in Table 4. We report case-sensitive SacreBLEU scores using SacreBLEU (Post, 2018) for EN-PL, DE-HSB, and BLEU based on characters for EN-ZH. In the results, "+" means addition based on baseline, and "++" means cumulative addition based on the previous one.

In PL→EN, the introduction of ParaCrawl data improves the baseline performance on the dev dataset by about 4.2 BLEU. +D2GPo, XLM-enhanced NMT, Bidirectional NMT, and ensembling outperforms our strong baseline by 2 BLEU point. Finally, finetuning and reranking further gives another 0.5 BLEU.

For EN→ZH, as with PL→EN, we see similar improvements with +D2GPo, XLM-enhanced NMT, ensembling and reranking. We also observe that the addition of Document-enhanced NMT is much more substantial, improving single model performance by over 1.5 BLEU.

In the unsupervised track, we compared CLM, MLM, and Explicit Sentence Compression (ESC) pre-training approaches joint trained with BT in the second stage of UNMT, respectively, and found that MLM and ESC had similar effects and were stronger than CLM. Moreover, the pre-training baseline of MLM was stronger than that of MASS. The combination of unsupervised training of DE-HSB and supervised training of EN-DE achieves the purpose of transfer learning, and the improvement is greater than 3 BLEU. Based on the conclusion of MLM and BT joint training on the UNMT Baseline, we also got a similar

[1]Our systems in unsupervised track are not a constrained unsupervised system due to the utilization of additional parallel corpora.

[2]The team name for PL→EN submission is "NICT-rui" in the OCELoT site to distinguish between different sub-teams.

Table 4: DE↔HSB low-resource performance (sacreBLEU score) for different models.

trend on the MUNMT system. In the final system, the enhancement of RAT+RABT+XBT brought a BLEU increase of 11.7 and 4.2, respectively.

In the low-resource track, the model in the unsupervised track is used as the pre-trained model, and DE-HSB NMT and BT are jointly trained. Due to the DE-HSB parallel corpus, we can not only use MLM for monolingual pre-training, but also use TLM for cross-lingual pre-training. The addition of CFST and D2GPo further improves the effect of the model, indicating that these contributions are orthogonal. In addition, comparing UNMT with MUNMT given a parallel corpus, we found that although MUNMT used more data, it did not bring about a large enough effect improvement, so we will leave it for future research.

5 Conclusion

This paper describes SJTU-NICT's submission to the WMT20 news translation task. For three typical scenarios, we adopt different strategies. In this work, we not only study the pre-trained language model to enhance MT, but also consider the impact of document information on translation. We considered both the way of converting document alignment into sentence alignment and the use of BERT's NSP to recover the structure of documents. In addition, transfer learning from supervision is taken into account in unsupervised translation, and various means are used to enhance low-resource translation. Our systems performed strongly among all the submissions: we ranked 1st in PL→EN, EN→ZH, and DE→HSB respectively, and stayed Top-3 for the HSB→DE.

Abstract

This paper presents neural machine translation systems and their combination built for the WMT20 English↔Polish and Japanese→English translation tasks. We show that using a Transformer Big architecture, additional training data synthesized from monolingual data, and combining many NMT systems through n-best list reranking improve translation quality. However, while we observed such improvements on the validation data, we did not observe similar improvements on the test data. Our analysis reveals that the presence of translationese texts in the validation data led us to take decisions in building NMT systems that were not optimal to obtain the best results on the test data.

1 Introduction

This paper describes the neural machine translation (NMT) systems and their combination built for a participation of the National Institute of Information and Communications Technology (NICT) in the WMT20 shared News Translation Task.[1] We participated in three translation directions: Japanese→English (Ja→En), English→Polish (En→Pl), and Polish→English (Pl→En). All our systems are *constrained*, i.e., we used only the parallel and monolingual data provided by the organizers to train and tune them, and validated/selected our best systems exclusively using the official validation data provided by the organizers. We trained NMT systems with several different frameworks and architectures, and combined them, for each translation direction, through n-best list reranking using informative features as proposed by Marie and Fujita (2018). This simple combination method, associated with the exploitation of large tagged back-translated monolingual data, improved BLEU scores on the official validation data provided by the organizers. However, we did not observe these improvements on the test data for which our baseline systems remained the best. While we have rigorously selected our systems according to their performance on the validation data, the analysis of our results reveal how easily we would have been able to achieve BLEU scores among the best submissions by choosing/selecting our best systems according to their performance on the test data, as encouraged by the WMT submission process (Section 2).

The remainder of this paper is organized as follows. In Section 2, we briefly describe the WMT20 translation task. In Section 3, we introduce the data pre-processing and cleaning. In Section 4, we describe the details of our NMT systems' architectures and frameworks. In Section 5, we describe two different strategies that we used to augment the training parallel data of our systems: parallel data extraction from monolingual data and backward/forward translations. Then, the combination of our NMT systems is described in Section 6. Empirical results produced with our systems on the validation and test data are presented in Section 7. We propose an analysis in Section 8 to better understand why our best systems on the validation data are significantly worse on the test data. Section 9 concludes this paper.

2 Description of the Task

The task is to translate texts in the news domain. For this purpose, news articles were sampled from online newspapers from September–November 2019. The sources of the test data are original texts whereas the targets are human-produced translations, i.e., participants are not asked to translate translationese texts unlike past WMT translation tasks. Although organizers also mentioned that the provided validation data were

[1] The team ID of our participation is "NICT_Kyoto".

Proceedings of the 5th Conference on Machine Translation (WMT), pages 230–238
Online, November 19–20, 2020.

created in the same way as the test data, they were actually made half of translationese texts and half of original texts. For the Inuktitut→English translation task, source texts to translate in the test data were only translationese texts.

Training parallel and monolingual data were provided for all language pairs. Participants were asked to mention whether they used additional external data. We chose to participate in the *constrained* settings using only the provided data to train our MT systems. Validation data were also provided for each language pair. We used the entire data to keep it sufficiently large for validation purposes, even though half of it was made up of translationese texts.

For collecting submissions, organizers relied on a new framework: `Ocelot`.[2] Each participant was allowed to submit up to 8 submissions per account but was not limited in the number of accounts. Upon submission, `Ocelot` shows the corresponding chrF and BLEU scores computed using reference translations that were not released during the competition. Participants could then rely on these scores to select and validate their best system on the test data.[3] We chose to ignore these scores obtained on the test data to remain in a much more realistic scenario where we do not have access to reference translations, i.e., we relied only on the validation data to select our primary submission.

Primary submissions selected by the participants were then evaluated by humans which is the official evaluation for WMT translation tasks.

3 Data Pre-processing and Cleaning

3.1 Data

As parallel data to train our systems, we used all the provided data for all our targeted translation directions, except the "Wiki Titles"[4] corpus. As English monolingual data, we used all the provided data, but sampled only 200M lines from the "Common Crawl" corpora, except the "News Discussions" and "Wiki Dumps" corpora. For all other languages, we used all the provided monolingual corpora but also sampled only 200M lines from the "Common Crawl" corpora.

To tune/validate and evaluate our systems, we used the official validation and test data provided by the organizers.

Language pair	#sent. pairs	#tokens	
En–Pl	8.7M	239.5M (En)	310.0M (Pl)
En–Ja	15.2M	394.5M (En)	380.6M (Ja)

Table 1: Statistics of our pre-processed parallel data.

3.2 Pre-processing and Cleaning

Since some corpora were crawled from the Web and therefore potentially very noisy, we first performed language identification on all the data to keep only lines that have a high probability of being in the right language. We used `fastText` (Bojanowski et al., 2017) and its large model for language identification.[5] We only retained sentences that have a probability higher than 0.75 to be in the right language. For the parallel data, if at least one side of each sentence pair did not match this criteria, we removed the pair from the corpus.

We used Moses (Koehn et al., 2007) punctuation normalizer, tokenizer, and truecaser for English and Polish. The truecaser was trained on the News Crawl 2019 corpora. Truecasing was then performed on all the tokenized data. Then, for the Pl–En language pair, we jointly learned 32k BPE operations (Sennrich et al., 2016b) on the concatenation of English and Polish News Crawl 2019 corpora. We performed sub-word segmentation using this vocabulary on the Polish and English parallel and monolingual data. For the Ja–En language pair, we independently learned 32k BPE operations on the English News Crawl 2019 corpus for English, 32k sentence piece (Kudo and Richardson, 2018) operations on the Japanese News Crawl 2019 corpus for Japanese, and then applied the operations to perform sub-word segmentation on the data in their respective language.

For further cleaning of the data, we applied the script "clean-corpus-n.perl" from Moses to remove empty lines and sentences longer than 120 sub-word tokens. Tables 1 and 2 present the statistics of the parallel and monolingual data, respectively, after pre-processing.

[2] https://ocelot.mteval.org/

[3] We can read in the "competition updates" that this behavior was encouraged by the organizers: "Also added chrF computation to give you more data points for your primary submission selection. Submissions remain ordered by decreasing SacreBLEU score."

[4] It contains only very short segments that are not sentences. We therefore assume to be of limited use in NMT.

Language	#lines	#tokens
En (En–Pl)	328M	7.9B
En (En–Ja)	328M	7.7B
Ja	184M	4.8B
Pl	137M	3.2B

Table 2: Statistics of our pre-processed monolingual data.

4 NMT systems

4.1 Architectures

Transformer Base and Big For our NMT systems, we chose the Transformer architecture (Vaswani et al., 2017). In this paper, we refer to Transformer Base and Big as the "*base*" and "*big*" configurations from Vaswani et al. (2017)'s paper. The architecture differences are as follows:

- Base: 512 embedding dimensions, 2,048 dimensions for the feed-forward, and 8 heads
- Big: 1024 embedding dimensions, 4,096 dimensions for the feed-forward, and 16 heads

Highway Transformer Residual connections (RCs) (Srivastava et al., 2015a; He et al., 2016) have been shown to increase forward and backward information flow in deep neural networks (Hardt and Ma, 2017) and thus are a crucial component of the Transformer architecture. Removing them has a negative impact on training and on the overall performances of the resulting model (Bapna et al., 2018). However, incorporating RCs through the addition operation as it is commonly done in the Transformer network does not allow for a distribution of weights between carrying or transforming the input. An alternative, inspired by the *Highway Network* (Srivastava et al., 2015b) and implemented within the Transformer by Chai et al. (2020), includes a trainable gating mechanism that regulates the information flow. We applied a few modifications to the implementation proposed in Chai et al. (2020): removing all layer normalization operations, adding depth-aware parameter initialization (Junczys-Dowmunt, 2019; Zhang et al., 2019), and initializing biases so that the residual blocks are initially forced to carry information rather than transforming it (Srivastava et al., 2015b).

4.2 Frameworks and Settings

`Marian` Our Models trained with the `Marian` toolkit (Junczys-Dowmunt et al., 2018) were only based on Transformer *Base*. We set the dropout at 0.1 and used the mini-batch-fit option of `Marian` to have batches as large as allowed by the size of the GPU memory. We used ReLU activation functions and optimized the models using the Adam optimizer with parameters $\beta_1 = 0.9$, $\beta_2 = 0.98$, and $\epsilon = 1e^{-9}$, a learning rate initialized at $3e^{-4}$, following a linear warm-up during 16k updates and decaying based on the inverse square root of the update number. Label smoothing was set to 0.1. During training, mean cross-entropy was evaluated on the entire validation data every 5,000 mini-batch updates and training was stopped after 5 consecutive times without an improvement of the mean cross-entropy. Then, we selected the best model that yielded the best BLEU score on the validation data. For decoding, we fixed the beam size at 12 and the length normalization at 1.0.

`Fairseq` Models trained with the `Fairseq` toolkit were based on Transformer *base* and Transformer *big*. The former used a dropout rate of 0.1 and batches containing approximately 12k tokens with parameters updated every 2 batches. The latter used a dropout rate of 0.3 and batches containing approximately 8k tokens with parameters updated every 8 batches. Both configurations shared decoder input and output embeddings, trained with half-precision float numbers, used ReLU activation functions, were optimized using the Adam optimizer with parameters $\beta_1 = 0.9$, $\beta_2 = 0.98$, and $\epsilon = 1e^{-9}$, a learning rate initialized at $1.7e^{-7}$, following a linear warm-up during 4k updates until reaching $5e^{-4}$ and decaying based on the inverse square root of the update number. Label smoothing with a parameter 0.1 was applied during training. Whereas *base* models were trained for 200 epochs, *big* models were trained for 100 epochs. The entire validation data was used for evaluation every epoch, while the best BLEU scores on this data allow for checkpoint saving. The parameters for decoding were fixed: a beam size of 4 and a length penalty of 0.6.

5 Training Data Augmentation

5.1 Parallel Data Alignment

We extracted additional training parallel data from the News Crawl monolingual corpora with the following procedure:

1. Jointly train bilingual word embeddings on

Configuration	En–Pl			Ja→En	#sent. pairs
	En→Pl	Pl→En	#sent. pairs		
w/o NC	26.3	30.4	0	20.3	0
w/ NC	26.4	30.6	257.4k	20.3	244.1k

Table 3: Results obtained on the validation data with `Fairseq` Big with and without using the additional parallel data extracted from the News Crawl monolingual corpora, denoted "NC." The columns "#sent. pairs" indicate how many sentence pairs were extracted from the News Crawl monolingual corpora.

the provided parallel data using `Bivec` (Luong et al., 2015).

2. Make all possible bilingual sentence pairs from News Crawl corpora in the source and target languages.

3. For each sentence pair, compute the similarity between the source and target sentences using the bilingual word embeddings trained with `Bivec` simply by measuring cosine similarity over the averaged word embeddings in each sentence as proposed by Artetxe and Schwenk (2019).[6]

4. Finally, keep only the sentence pairs with a score higher than a threshold among $\{1.0, 1.0025, 1.05\}$ and select the value that results in the sentence pairs leading to the highest BLEU score on the validation data when mixing the selected sentence pairs with the original parallel data for training NMT.

Table 3 gives an overview of the results obtained with the additional sentence pairs extracted from News Crawl. We did not observe significant improvements as we could only extract a very small amount of useful sentence pairs. Nevertheless, we decided to keep these additional data to train our other NMT systems, since it did not appear harmful according to BLEU. However, as we report in Section 8, it was not the optimal choice to obtain the best results on the test data.

5.2 Backward and Forward Translation of Monolingual Data

Parallel data for training NMT can be augmented with synthetic parallel data, generated through a so-called back(ward)-translation, to significantly improve translation quality (Bertoldi and Federico, 2009; Bojar and Tamchyna, 2011; Sennrich et al., 2016a). We used the `Fairseq` Big system, trained on the provided parallel data and the aligned News Crawl sentence pairs, to translate target monolingual sentences into the source language. Then, these back-translated sentences were simply mixed with the original parallel data, putting the synthetic side on the source side, to train from scratch a new NMT system.

We also experimented with forward translation, i.e., with the synthetic part on the target side, and tagged back-translation (Caswell et al., 2019), which simply adds a tag at the beginning of each back-translation, as it has shown to lead to better results, especially when translating texts in their original language (Marie et al., 2020).

For English, we translated 50M sentences made of the entire News Crawl 2019 corpus and randomly added sentences from News Crawl 2018 corpus until we have 50M sentences. For Polish and Japanese, we translated the entire News Crawl corpora and added sentences from the Common Crawl corpus until we have 50M sentences.

For each configuration, i.e., back-translation, tagged back-translation, and forward translation, we also experimented with sub-samples of 12.5M (only with `Marian`), and 25M synthetic sentence pairs, in addition to using the entire 50M sentence pairs, for retraining the NMT systems. Table 4 gives an overview of the results for each configuration obtained on the validation data.

All configurations using back-translations (BT) and tagged back-translations (TBT) were better than the baseline system as expected. We also observed very small differences in BLEU when increasing the size of the back-translated data.

TBT improves over BT as expected (Caswell et al., 2019), but only for Pl→En and Ja→En. On the other hand, using forward translations significantly decreased BLEU scores, as expected, since it introduces NMT translations to the target side of the training data (Bogoychev and Sennrich, 2019), but again only for Pl→En and Ja→En. Our results for En→Pl across all configurations remained similar, which defies the findings of previous work on back-translation and forward translation. We give

[6] We used the "Ratio" version of the scoring function.

System	#sent. pairs	En→Pl	Pl→En	Ja→En
Marian Base	0	24.4	29.1	18.1
BT	12.5M	26.1	32.1	21.1
	25M	26.2	32.1	21.2
	50M	26.3	31.7	21.1
TBT	12.5M	26.1	30.3	21.1
	25M	26.1	32.3	21.2
	50M	26.3	32.2	21.4
FWD	12.5M	26.3	29.7	18.3
	25M	26.4	29.5	17.4
	50M	26.3	29.6	16.4

Table 4: Results of Marian Base on the validation data obtained using synthetic parallel data as back-translations (BT), tagged back-translations (TBT) or forward translations (FWD).

Feature	Description
NMT models	Scores given by each NMT model
LEX	Sentence-level translation probabilities, for both translation directions
LM	Scores given by a 4-gram language model trained on all the monolingual corpora in the target language
LEN	Difference between the length of the source sentence and the length of the translation hypothesis, and its absolute value

Table 5: Set of features used by our reranking systems. The "Feature" column refers to the same feature used in Marie and Fujita (2018). The numbers between parentheses indicate the number of scores in each feature set.

some plausible explanations for this peculiarity in our analysis in Section 8.

6 Combination of NMT systems

Our primary submissions for the tasks were the result of a simple combination of all our NMT systems through n-best list reranking. As demonstrated by Marie and Fujita (2018), it can significantly improve translation quality, even when there is a large difference in translation quality between the combined systems. Following Marie and Fujita (2018), our system combination works as follows.

6.1 Generation of n-best Lists

We first independently generated the 100-best translation hypotheses from each of all our NMT models, and additional 12-best, with Marian, or 4-best with Fairseq. We then merged all these lists generated by different systems, without removing duplicated hypotheses.

6.2 Reranking Framework and Features

We rescored all the hypotheses in the list with a reranking framework using features to better model the fluency and the adequacy of each hypothesis. This method can find a better hypothesis in these merged n-best lists than the one-best hypothesis originated by the individual systems. We chose KB-MIRA (Cherry and Foster, 2012) as a rescoring framework and used a subset of the features proposed in Marie and Fujita (2018). All the following features we used are described in detail by Marie and Fujita (2018). As listed in Table 5, it includes all scores given by all our NMT models. We computed sentence-level translation probabilities using the lexical translation probabilities learned by mgiza on all the parallel training data of our NMT systems. One 4-gram language model trained on the target language model was also used. To account for hypotheses length, we added the difference, and its absolute value, between the number of tokens in the translation hypothesis and the source sentence. The reranking framework was trained on n-best lists generated by decoding the entire validation data.

7 Results

Our main results are presented in the Table 6. According to the validation data, Fairseq Base is as good as, or better than, Marian Base. Given this observation, we trained Fairseq Big and obtained even better results on the validation data. BLEU scores are improved by up to 4.1 BLEU points when using tagged back-translations (TBT) on the validation data. Overall, the best system is, as expected, the Reranker combining all our systems with additional features. How-

System	En→Pl		Pl→En		Ja→En	
	Validation	Test	Validation	Test	Validation	Test
Marian Base	24.4	21.2	29.1	31.9	18.1	19.1
Fairseq Base	24.4	21.8	30.3	32.4	19.4	18.7
Fairseq Big	26.4	21.9	30.9	31.5	20.4	19.3
Fairseq Big TBT	28.5	23.1	35.0	31.8	23.3	19.9
Reranker∗	29.9	24.9	36.5	32.3	25.5	22.8

Table 6: Results of our main systems. Marian Base and Fairseq Base use the same training data and architecture. Fairseq Big uses Transformer Big and the additional training data extracted from News Crawl corpora. Fairseq Big TBT is retrained from scratch on the tagged back-translations generated by Fairseq Big. The system denoted with an "∗" is our primary system.

ever, surprisingly, the results on the test data exhibited a significantly different pattern. For instance, Marian Base performed very closely to Fairseq Big on the test data. Even more strikingly, we observed only small differences in BLEU between Fairseq Big and Fairseq TBT. For instance, for Pl→En, while we have 4.1 BLEU points of improvements on the validation data, we have only 0.3 BLEU points of improvements on the test data. Also for this translation direction, Reranker outperforms Marian Base by 7.4 BLEU points on the validation data but by only 0.4 BLEU points on the test data.

To better understand the lack of correlation between our results on validation and test data, we propose an analysis in the next section.

8 Analysis

Table 7 presents all our results for En↔Pl on the validation data, separating the part in the original and non-original languages, and the test data.

One obvious observation from these results is that the BLEU scores on the test data are all very close to the score of the validation data in original language (Orig.). On the other hand, we also observe that the ranking of the systems given the BLEU score on the entire validation data does not correlate well with the ranking of the systems given the BLEU score on the validation data in the original language. It means that the translationese texts in the validation data had a negative impact on all our decisions for selecting the best framework, architecture, additional parallel sentences, and so forth, and that we could potentially had better results by taking our decisions by using only the original texts in the validation data.

Translationese texts are particularly harmful for training a Reranker, as we can observe for Pl→En. Using them as training data for the Reranker leads to significantly lower BLEU scores (#14) while training it only on the original texts of the validation data leads to our best BLEU score (#15). For this translation direction, we also observe large improvements of BLEU thanks to back-translations on the validation data that comes mainly from the translationese texts while translation quality drops when translating the original texts in the validation and test data, as expected. This was compensated by using tagged back-translations (#10-12) as suggested by Marie et al. (2020).

Our observations are very different for the reverse translation direction. For En→Pl, training Reranker on the entire validation data leads to the best BLEU score, and it drops only slightly when training only on the translationese texts. Even more surprisingly, using back-translations improves BLEU scores for both original and translationese texts while using tagged back-translations (#12) leads to BLEU scores identical to those obtained by using back-translations (#9) for the original texts. These peculiarities observed for Pl→En, associated with our observations in Section 5.2 that forward translations improves BLEU, are in contradiction with the findings in previous work as follows.

- Back-translations should decrease BLEU scores for original texts (Edunov et al., 2020).
- Tagged back-translations should improve BLEU scores for original texts (Marie et al., 2020).
- Forward translation should lead to lower BLEU scores for translationese texts (Bogoychev and Sennrich, 2019).

A possible explanation is that the texts denoted as "original" in the validation data and the test data,

#	System	Arch.	NC	BT	TBT	En→Pl Validation Orig.	En→Pl Validation Non-orig.	En→Pl Validation All	En→Pl Test	Pl→En Validation Orig.	Pl→En Validation Non-orig.	Pl→En Validation All	Pl→En Test

"Reranker Non-orig." and "Reranker Orig." are variants of Reranker that are trained on the validation data using only the part in the non-original and original languages, respectively, while Reranker, our primary system, was trained on the entire validation data.

that were prepared similarly, do have some characteristics of translationese that may come from the translation of texts not in their original language or the use of MT followed by post-editing. Comparing our results with the results of other participants will help us test this assumption.

9 Conclusion

We participated in three translation directions and for all of them we did experiments with several frameworks and architectures, also exploiting additional synthetic parallel data made from monolingual data. Combining all our systems led to significantly better BLEU scores on the validation data. However, our analysis revealed that the presence of translationese texts in the validation data led us to take sub-optimal choices that prevented us from obtaining significantly better BLEU scores on the test data. Selecting/validating systems on the test data should not be possible, or at least not an option. We thus suggest organizers to provide validation data that better matches the characteristics of the test data, e.g., removing translationese texts if none are in the test data.

Acknowledgments

We would like to thank Reviewer 1 for the detailed corrections and suggestions.

Abstract

We participate in the WMT 2020 shared news translation task on Chinese→English. Our system is based on the Transformer (Vaswani et al., 2017) with effective variants and the DTMT (Meng and Zhang, 2019) architecture. In our experiments, we employ data selection, several synthetic data generation approaches (i.e., back-translation, knowledge distillation, and iterative in-domain knowledge transfer), advanced finetuning approaches and self-bleu based model ensemble. Our constrained Chinese→English system achieves 36.9 case-sensitive BLEU score, which is the highest among all submissions.

1 Introduction

Our WeChat AI team participates in the WMT 2020 shared news translation task on Chinese→English. In this year's translation task, we mainly focus on exploiting several effective model architectures, better data augmentation, training and model ensemble strategies.

For model architectures, we mainly exploit two different architectures in our approaches, namely Transformers and RNMT. For Transformers, we implement the Deeper transformer with Pre-Norm, the Wider Transformer with a larger filter-size and the average attention based transformer (Zhang et al., 2018). For the RNMT, we use the deep transition based DTMT (Meng and Zhang, 2019) model. We finally ensemble four kinds of models in our system.

For synthetic data generation, we explore various methods for out-of-domain and in-domain data generation. For out-of-domain data generation, we explore the back-translation method (Sennrich et al., 2016a) to leverage the target side monolingual data and the knowledge distillation method (Kim and Rush, 2016) to leverage the source side of golden parallel data. For in-domain data generation, we employ iterative in-domain knowledge transfer to leverage the source-side monolingual data and golden parallel data. Furthermore, data augmentation methods, including noisy fake data (Wu et al., 2019) and sampling (Edunov et al., 2018), are used for training more robust NMT models.

For training strategies, we mainly focus on the parallel scheduled sampling (Mihaylova and Martins, 2019; Duckworth et al., 2019), the target denoising and minimum risk training (Shen et al., 2016; Wang and Sennrich, 2020) algorithm for in-domain finetuning.

We also exploit a self-bleu (Zhu et al., 2018) based model ensemble approach to enhance our system. As a result, our constrained Chinese→English system achieves the highest case-sensitive BLEU score among all submitted systems.

In the remainder of this paper, we start with an overview of model architectures in Section 2. Section 3 describes the details of our systems and training strategies. Then Section 4 shows the experimental settings and results. Finally, we conclude our work in Section 5.

2 Model Architectures

In this section, we first describe the model architectures we use in the Chinese→English Shared Task, including the Transformer-based (Vaswani et al., 2017) models and RNN-based (Bahdanau et al., 2014; Meng and Zhang, 2019) models.

2.1 Deeper Transformer

As shown in previous studies (Wang et al., 2019; Sun et al., 2019), deeper Transformers with pre-norm outperform its shallow counterparts on various machine translation benchmarks. In their work, increasing the encoder depth significantly improves the model performance, while they only introduce mild overhead in terms of speed in training and

Proceedings of the 5th Conference on Machine Translation (WMT), pages 239–247
Online, November 19–20, 2020.

inference, compared with increasing the decoder side depth.

Hence, we train deeper Transformers with a deep encoder aiming for a better encoding representation. In our experiments, we mainly adopt two settings, with the hidden size 512 (Base) and 1024 (Large). We adopt a 30-layer encoder for Base models and 20/24-layer encoders for Large models. Further increasing the encoder depth does not lead to a significant BLEU improvement. To keep the total trainable parameters the same among models, the filter sizes of Base and Large models are 16384 and 4096, respectively. For training, the batch size is 4,096 tokens per GPU, and we train each model using 8 NVIDIA V100 GPUs for about 7 days.

2.2 Wider Transformer

Inspired by last year's Baidu system (Sun et al., 2019), we also train Wider Transformers with a larger inner dimension of the Feed-Forward Network than the standard Transformer Large system. Specifically, two settings are used in our experiments. With a filter size of 15,000, we set the number of encoder layers to 10, and with a filter size of 12,288, we set the number of encoder layers to 12. The number of total trainable parameters of the Wider Transformer is kept approximately the same as our Deeper Transformers.

In our experiments, we also set the batch size to be 4,096 and train the Wider Transformers with 8 NVIDIA V100 GPUs for about 7 days.

2.3 Average Attention Transformer

To introduce more diversity in our Transformer models, we use Average Attention Transformer (AAN) (Zhang et al., 2018) as one of our candidate architectures. The Average Attention Transformer replaces the decoder self-attention module in auto-regressive order with a simple average attention, and introduces almost no loss in model performance.

We believe that even though the performance of AAN does not drop in terms of BLEU, the output distributions of AAN networks should be different from the output distributions of original Transformers, which brings diversity for the final ensemble. This also complies with our findings in self-bleu experiments (Section 3.6).

In practice, AAN models are trained for both the Wider Transformer and Deeper Transformer. The batch size and other hyper-parameters are kept the same as its non-AAN counterpart.

2.4 DTMT

DTMT (Meng and Zhang, 2019) is the recently proposed deep transition RNN-based model for Neural Machine Translation, whose encoder and decoder are composed of the well-designed transition blocks, each of which consists of a linear transformation enhanced GRU (L-GRU) followed by several transition GRUs (T-GRUs). DTMT enhances the hidden-to-hidden transition with multiple non-linear transformations, as well as maintains a linear transformation path throughout this deep transition by the well-designed linear transformation mechanism to alleviate the vanishing gradient problem. This architecture has demonstrated its superiority over the conventional Transformer model and stacked RNN-based models in NMT (Meng and Zhang, 2019), and also achieves surprising performances on other NLP tasks, such as sequence labeling (Liu et al., 2019) and aspect-based sentiment analysis (Liang et al., 2019).

In our experiments, we use the bidirectional deep transition encoder, where each directional deep transition block consists of 1 L-GRU and 4 T-GRU. The decoder contains a query transition block and the decoder transition block, each of which consists of 1 L-GRU and 4 T-GRU. Therefore the DTMT consists of a 5 layer encoder and a 10 layer decoder, with a hidden size of 1,024. We use 8 NVIDIA V100 GPUs to train each model for about three weeks and the batch size is set to 4,096 tokens per GPU.

3 System Overview

In this section, we describe our system used in the WMT 2020 news shared task.

Figure 1 depicts the overview of our Wechat NMT. Our system can be divided into four parts, namely data filtering, synthetic data generation, in-domain finetuning, and ensemble. The synthetic generation part further includes the generation of out-of-domain and in-domain data. Next, we will illustrate these four parts.

3.1 Data Filter

Following previous work (Li et al., 2019), we filter the training bilingual corpus with the following rules:

- Normalize punctuation with Moses scripts.
- Filter out the sentences longer than 100 words, or exceed 40 characters in a single word.

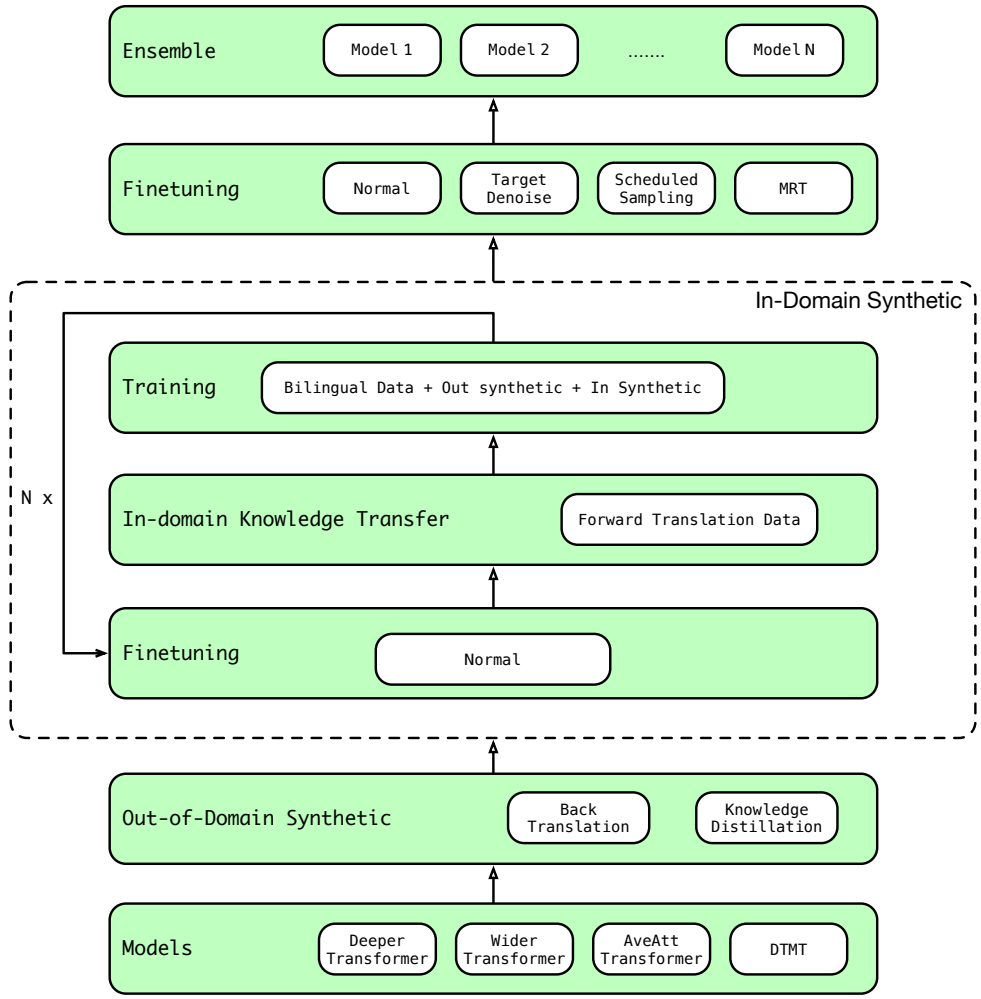

Figure 1: Architecture of WeChat NMT system. For simplicity, the data filtering module is ignored in the overview.

	NUM
Bilingual Data	20.7M
Chinese Monolingual Data	153.5M
English Monolingual Data	121.2M

Table 1: Statistics of all training data.

- Filter out the duplicated sentence pairs.
- The word ratio between the source and the target words must not exceed 1:4 or 4:1.

We also filter the monolingual corpus with the language model trained by the corresponding data of the bilingual training corpus.

In our experiments, the bilingual training data is a combination of News Commentary v15, Wiki Titles v2, WikiMatrix, CCMT and the UN corpus. The Chinese monolingual data includes News crawl, News Commentary, Common Crawl and Gigaword corpus. The English monolingual data includes News crawl, News discussions, Europarl v10, News Commentary, Common Crawl, Wiki dumps and the Gigaword corpus. After data filtering, statistics of all training data are shown in Table 1.

3.2 Out-of-Domain Synthetic Data Generation

Now, we describe our techniques for constructing both out-of-domain and in-domain synthetic data. The out-of-domain synthetic corpus is generated via both large-scale back-translation and knowledge distillation to enhance the models' performance for all domains. Then, we propose iterative in-domain knowledge transfer, which transfers in-domain knowledge to the huge monolingual corpus (i.e., Chinese), and builds our in-domain synthetic corpus. In the following sections, we elaborate above techniques in detail.

3.2.1 Large-scale Back-Translation

Back-translation is shown to be very effective to boost the performance of NMT models in both academic research (Hoang et al., 2018; Edunov et al., 2018) and previous years' WMT competitions (Deng et al., 2018; Sun et al., 2019; Ng et al., 2019; Xia et al., 2019). Following their work, we also train baseline English-to-Chinese models with the parallel data provided by WMT2020. Both the Left-to-Right Transformer (L2R) and the Right-to-Left Transformer (R2L) are used to translate the filtered monolingual English corpus combined with the English side of golden parallel bitext to Chinese. Then the generated Chinese text and the original English text are regarded as the source side and target side, respectively.

In practice, it costs us 7 days on 5 NVIDIA V100 GPU machines to generating all back-translated data.

3.2.2 Knowledge Distillation

Knowledge distillation (KD) is proven to be a powerful technique for NMT (Kim and Rush, 2016) to transfer knowledge from the teacher model to student models. In particular, we first use the teacher models to generate synthetic corpus in the forward direction (i.e., Chinese→English). Then, we use the generated corpus to train our student models.

In this work, with baseline Chinese→English models (i.e., L2R and R2L) as teacher models, we translate the Chinese sentences of the parallel corpus to English to form our synthetic KD dataset. The knowledge distillation costs about 2 days on 2 NVIDIA V100 GPU machines to generate all synthetic data.

3.3 Iterative In-domain Knowledge Transfer

Since in-domain finetuning demonstrates substantial BLEU improvements (Sun et al., 2019; Li et al., 2019), we speculate that the parallel data and the dev/test sets fall in different domains. Therefore, adapting our models to the target domain in advance will provide gains over the dev/test sets and give a better initialization point for in-domain finetuning. To this end, we use knowledge transfer to inject more in-domain information into our synthetic data.

In particular, we first use normal finetuning (see Section 3.5) to equip our models with in-domain knowledge. Then, we ensemble these models and use the ensemble model to translate the Chinese monolingual corpus into English. For our ensemble translator, we use 4 models with different architectures. Next, we pair original Chinese sentences with generated in-domain pseudo English sentences to form a pseudo parallel corpus. So far, the in-domain knowledge from ensembled models is transferred to the generated pseudo-parallel corpus. Finally, we retrain our model with both the in-domain pseudo-parallel and out-of-domain parallel data.

We refer to the above process as the in-domain knowledge transfer. In our experiments, we find that iteratively performing the in-domain knowledge transfer can further provide improvements (see Table 2). For each iteration, we replace the in-domain synthetic data and retrain our models, and it costs about 10 days on 8 NVIDIA V100 GPU machines. For the final submission, the knowledge transfer is conducted twice.

3.4 Data Augmentation

Aside from synthetic data generation, we also apply two data augmentation methods over our synthetic corpus. Firstly, adding synthetic/natural noises to training data is widely applied in the NLP fields (Li et al., 2017; Belinkov and Bisk, 2017; Cheng et al., 2019) to improve model robustness and enhance model performance. Therefore, we proposed to add token-level synthetic noises. Concretely, we perform random replace, random delete, and random permutation over our data. The probability of enabling each of the three operations is 0.1. We refer to this corrupted corpus as *Noisy* data.

Secondly, as illustrated in (Edunov et al., 2018), sampling generation over back-translation shows its potential in building robust NMT systems. Consequently, we investigate the performance of sampled synthetic data. For back-translated data, we replace beam search with sampling in its generation. For in-domain synthetic data, we replace the golden Chinese with the back sampled pseudo Chinese sentences. We refer to the data with sampling generation as *Sample* data.

As a special case, we refer to the without augmentation data as *Clean* data.

3.5 In-domain Finetuning

We train the model on large-scale out-of-domain data until convergence and then finetune it on small-scale in-domain data, which is widely used for domain adaption (Luong and Manning, 2015; Li et al., 2019). Specifically, we take Chinese→English test sets of WMT 17 and 18 as in-domain data, and filter out documents that are originally created in

English (Sun et al., 2019). We name above finetuning approach as *normal* finetuning. In all our finetuning experiments, we set the batch size to 4096, and finetune the model for around 400 steps[1] on the in-domain data.

Furthermore, the well-known problem of exposure bias in sequence-to-sequence generation becomes more serious under domain shift (Wang and Sennrich, 2020). To solve this issue, we further explore some *advanced* finetuning approaches and describe details in the following paragraphs.

Parallel Scheduled Sampling. We apply a two-pass decoding strategy for the Transformer decoder when finetuning, which is named as parallel scheduled sampling (Mihaylova and Martins, 2019; Duckworth et al., 2019). In the first pass, we obtain model predictions as a standard Transformer, and then mix the predicted sequence with the golden target sequence. In the second pass, we feed the above mixture of both golden and predicted tokens as decoder inputs for the final prediction. Thus the problem of the training-generation discrepancy is alleviated in the finetuning stage. According to our preliminary experiments, we set the proportion of predicted tokens in mixed tokens to 50%.

Target Denoising. In the training stage, the model never sees its own errors. Thus the model trained with teacher-forcing is prone to accumulated errors in testing (Ranzato et al., 2015). To mitigate this training-generation discrepancy, we add noisy perturbations into decoder inputs when finetuning. Thus the model becomes more robust to prediction errors by target denoising. Specifically, the finetuning data generator chooses 30% of sentence pairs to add noise, and keeps the remaining 70% of sentence pairs unchanged. For a chosen pair, we keep the source sentence unchanged, and replace the i-th token of the target sentence with (1) a random token of the current target sentence 15% of the time (2) the unchanged i-th token 85% of the time.

Minimum Risk Training. To further avoid the problem of exposure bias, we propose to use minimum risk training (Shen et al., 2016) in the finetuning stage, which directly optimizes the expected BLEU score instead of the Cross-Entropy loss, and naturally avoids exposure bias. Specifically, the objective is computed by,

$$R(\theta) = \sum_{s=1}^{S} \sum_{y \in S(x^{(s)})} Q(y|x^{(s)};\theta,\alpha)\Delta(y, y^{(s)}), \tag{1}$$

where $x^{(s)}$ and $y^{(s)}$ are two paired sentences. Δ denotes a risk function and $S(x^{(s)}) \in Y$ is a sampled subset of full search space. Then, the distribution Q is defined over space $S(x^{(s)})$,

$$Q(y|x^{(s)};\theta,\alpha) = \frac{P(y|x^{(s)};\theta)^{\alpha}}{\sum_{y' \in S(x^{(s)})} P(y'|x^{(s}};\theta)^{\alpha}}. \tag{2}$$

In practice, we use 4 candidates for each source sentence $x^{(s)}$. Although the paper claimed that sampling generates better candidates, we find that the beam search performs better in our extremely large Transformer model. The risk function we used is the 4-gram sentence-level BLEU (Chen and Cherry, 2014) and we tune the optimal α via grid search within $\{0.005, 0.05, 0.5, 1, 1.5, 2\}$. Each model is fine-tuned for a max of 1000 steps.

3.6 Ensemble

We split each training data into three shards among *Clean*, *Noisy* and *Sample* data respectively, which yields a total number of 9 shards. For each shard, we train seven varieties (two Deeper transformers, two Wider transformers, two AANs and one DTMT) with different model architecture. Then we apply four finetuning approaches on each model, thus the total number of models is quadrupled (about 200 models). For ensemble, it is difficult and inefficient to enumerate over all combinations of candidate models (e.g., grid search). Therefore a pruning strategy for model selection is necessary when ensemble. We try to greedily select the top-performing models for the ensemble. However, only slight improvement is obtained (less than 0.1 BLEU), as our models are too similar to each other after finetuning.

To further promote diversity among candidate models, we propose the self-bleu driven pruning strategy for *advanced* ensemble. Specifically, we take the translations of one model as hypotheses and translations of other models as references. Then we calculate the BLEU score for each model to evaluate its diversity among other models. Models with small BLEU scores are selected for ensemble, and vice versa. According to our experiments, we observe that (1) AAN and DTMT show

[1] According our experiments, finetuning with more steps will make the model easy to overfit on the small in-domain data.

SETTINGS	DEEPER	WIDER	AVEATT	DTMT
Baseline	26.24	26.35	26.17	26.08

Minimum Risk Training	**39.08**	**39.12**	38.78	38.45

Table 3: Case-sensitive BLEU scores (%) on the Chinese→English *newstest2019* for different finetuning approaches after the 2nd in-domain knowledge transfer. For each model architecture, we report the highest score among three shards of clean data and bold the best result among different finetuning approaches.

a clear difference with other architectures; (2) data sharding is effective to promote diversity, especially for models trained with *Clean* data; (3) different finetuning approaches cannot bring diversity for the same model. Under the guidance of self-bleu scores, our *advanced* ensemble models consist of 20 single models with differences in model architectures, data types, shards and finetuning approaches. As shown in Table 2, the *advanced* ensemble achieves absolute improvements over the normal ensemble (up to 0.7 BLEU improvements).

4 Experiments

4.1 Settings

All of our experiments are carried out on 15 machines with 8 NVIDIA V100 GPUs each of which has 32 GB memory. We use cased BLEU scores calculated with Moses[2] mteval-v13a.pl script as evaluation metric. *newstest2019* is used as the development set. For all experiments, we use LazyAdam optimizer with $\beta_1 = 0.9$, $\beta_2 = 0.998$ and $\epsilon = 10^{-9}$. The learning rate is set to 2.0 and decay with training steps. We use warmup step = 8000. We set beam size to 4 and alpha to 0.6 during decoding.

[2]http://www.statmt.org/moses/

4.2 Pre-processing and Post-processing

We segment the Chinese sentences with an in-house word segmentation tool. For English sentences, we successively apply punctuation normalization, tokenization and truecasing with the scripts provided in Moses. To enable open-vocabulary, we use byte pair encoding BPE (Sennrich et al., 2016b) with 32K operations for both Chinese and English sides.

For the post-processing, we apply de-truecaseing and de-tokenizing on the English translations with the scripts provided in Moses.

4.3 Main Results

Table 2 shows that the translation quality is largely improved with proposed techniques. We observe a solid improvement of 2.8∼3.4 BLEU for the baseline system after back translation. In-domain finetuning yields substantial improvements among all model architectures, which are 6.07∼6.32 BLEU. The finetuned Transformer models achieve about 35.89 BLEU scores, and the DTMT achieves a 35.03 BLEU score. These findings demonstrate that the domain of training corpus is apart from the target domain, and hence domain adaptation has great potential in improving model performance in the target domain.

As described in Section 3.3, we inject the in-domain knowledge into our monolingual corpus.

Two In-domain knowledge transfers provide another up to 3.02 BLEU score gain (i.e., from about 35.03 to 38.05). The in-domain knowledge transfer brings more improvement compared with the normal finetuned models. Besides, we find that models further finetuned after in-domain transfer performs slightly better (about 0.1 BLEU). The improvement suggests that although in-domain transfer has already provided plenty of in-domain knowledge, it still has room for in-domain finetuning. We further apply *advanced* finetuning techniques to our models, as described in Section 3.5. The advanced finetuning further brings about 0.81 BLEU score gains, and we obtain our best single model with 39.12 BLEU scores.

In our preliminary ensemble experiments, we combine some top-performing models at each decoding step, but only achieve slight improvement over single models (about 0.1 BLEU). With our *advanced* ensemble strategies in section 3.6, further improvements are achieved over the normal ensemble (0.7 BLEU). As a result, our WMT 2020 Chinese→English submission achieves a cased BLEU score of 36.9 on *newstest2020*, which is the highest among all submissions.

4.4 Effects of Advanced Finetuning Approaches

In this section, we describe our experiments on advanced finetuning. Here we take clean models as examples, but models trained with noisy data and sampled data show similar trends.

As shown in Table 3, all three advanced finetuning methods significantly outperform normal finetuning. For Wider and Deeper Transformers, Minimum Risk Training provides the highest BLEU gain, which is 0.81. For the Average Attention Transformer, Parallel Schedule Sampling improves the model performance from 38.38 to 38.93. For the DTMT model, Target Denoising performs the best, improving from 38.12 to 38.66. These findings are in line with the conclusion of Wang and Sennrich (2020) that links exposure bias with domain shift. For each type of model, we only keep the best-performing finetuned one for the final model ensemble.

5 Conclusion

In this paper, we introduce the system WeChat submitted for the WMT 2020 shared task on Chinese→English news translation. Our system is based on the Transformer (Vaswani et al., 2017) with different variants and the DTMT (Meng and Zhang, 2019) architecture. Data selection, several effective synthetic data generation approaches (i.e., back-translation, knowledge distillation, and iterative in-domain knowledge transfer), advanced finetuning approaches (i.e., parallel scheduled sampling, target denoising, and minimum risk training) and self-bleu based model ensemble are employed and proven effective in our experiments. Our constrained Chinese→English system achieved 36.9 case-sensitive BLEU score which is the highest among all submissions.

Alexander.Molchanov@promt.ru

Abstract

This paper describes the PROMT submissions for the WMT 2020 Shared News Translation Task. This year we participated in four language pairs and six directions: English-Russian, Russian-English, English-German, German-English, Polish-English and Czech-English. All our submissions are MarianNMT-based neural systems. We use more data compared to last year and update our back-translations with better models from the previous year. We show competitive results in terms of BLEU in most directions.

1 Introduction

This paper provides an overview of the PROMT submissions for the WMT 2020 Shared News Translation Task. This year we participate with neural MT systems for the third time. We participate in four language pairs and six directions. We describe our data preparation pipelines, models training setups and present the results on the newstest sets.

The paper is organized as follows: Section 2 is a brief overview of the submitted systems. Section 3 describes the data preparation, preprocessing and statistics in detail. Section 4 provides a detailed description of the systems. In Section 5 we present and discuss the results. Section 6 concludes the paper.

2 Systems overview

We submitted six systems based on the `MarianNMT` (Junczys-Dowmunt et al., 2018) toolkit: English-Russian, Russian-English, English-German, German-English, Polish-English and Czech-English. All systems are unconstrained (we use the allowed data, private data and publicly available unconstrained data like OpenSubtitles). The English-German and German-English systems have the same basic architecture. The English-Russian and Russian-English systems are slightly different as we use separate vocabularies. The Polish-English system was trained jointly in both directions. The Czech-English is a multilingual system trained to translate from Croatian, Serbian, Slovak and Czech to English.

3 Data

We use all data provided by the WMT organizers, private in-house parallel data and other publicly available data, mainly from the OPUS website (Tiedemann, 2012). The human parallel data for the German-English system is exactly the same as for the English-German system, the two systems only have different synthetic back-translated data. This also applies to the English-Russian and Russian-English systems.

We use the Tatoeba sets as our validation sets and the newstest2019 is our test set. The reason why we choose the Tatoeba corpus for validation is that we aim at building general-domain (and not just news-domain) models. Besides, the Tatoeba corpus is available for many language pairs beyond the scope of the WMT Translation Task.

We only do fine-tuning for the Czech-English system. This will be described in detail in Section 3.4 below.

3.1 Data filtering

There are several stages in our data filtering pipeline. The statistics for the final training data are shown in Table 1. Note that for the multilingual Czech|Croatian|Serbian|Slovak-English system the table provides statistics only for the Czech-English part. The size of the filtered versions of the Croatian, Serbian and Slovak parts

Proceedings of the 5th Conference on Machine Translation (WMT), pages 248–253

are 21.8M, 21.7M and 14M parallel sentences respectively (more than 95% of the Serbian data is OpenSubtitles).

Basic filtering

This includes some simple length-based and source-target length ratio-based heuristics, removing tags, lines with low amount of alphabetic symbols etc. We also remove lines which appear to be emails or web-addresses. In addition, we remove lines with rare words from the Bookshop and the OpenSubtitles corpora (using frequency lists built on large monolingual corpora including all monolingual data from WMT, private data and Wikipedia dumps).

Deduplication

We remove duplicate translations and keep only the most frequent translation for the source sentence if it repeats more than two times. This procedure is applied to some corpora, e.g. OpenSubtitles and MultiUN which contain a lot of various (and often incorrect) translations for common phrases. For example, the English phrase '*No.*' is encountered almost 100k times in the source side of the English-Russian OpenSubtitles corpus. It has more than 78k unique translations, second most popular among which is '*Да.*' ('*Yes.*' in Russian).

Language detection

The algorithm is a fairly simple ensemble of three tools: `pycld2` [1], `langid` (Lui and Baldwin, 2012), `langdetect` [2].

Parallel data filtering with NMT and language models

We apply this step to all data. Last year we used our own algorithm based on `Hunalign` (Varga et al., 2005) and our inhouse classifier to identify and discard unparallel sentence pairs. This year we use a different approach. We score parallel data with NMT models in both directions. We also score the source and target sides of the data with statistical language models built on large sets of what we assume to be good-quality data (basically, the newscrawl data from the statmt.org website). The scores are normalized by sentence length and summed up. We also apply weights (from 0.1 to 0.3 depending on the corpus type) to the statistical LMs scores as we mostly rely on the scores produced by the NMT models. The data is then sorted according to the final scores, and we select a subset of the data according to a certain threshold set individually for different corpora by our linguists.

	German-English		Russian-English		Polish-English		Czech-English	
	#sent	#tokens EN	#sent	#tokens EN	#sent	#tokens EN	#sent	#tokens EN
WMT	26.6	580.1	27.3	690.9	10.3	183.2	11.4	147.8
OPUS	23.8	475.9	8.3	74.9	26.8	283.7	29.1	263.8
Private	7.5	100.4	25.5	428.2	0.3	3.7	0.4	5.1
Total	57.9	1156.4	61.1	1194.0	37.4	470.6	40.9	416.7

Table 1: Statistics for the filtered parallel data in millions of sentences (#sent) and tokens (#tokens) for four language pairs. WMT stands for the data available for the News Task on the statmt.org/wmt20 website; OPUS is the data from the OPUS website apart from the data available for the News Task; Private stands for private company data.

3.2 Data preprocessing

BPE

Same as last year, we use the `OpenNMT` toolkit (Klein et al., 2017) version of byte pair encoding (BPE) (Sennrich et al., 2016b) to encode our data to subword units. The BPE merge operations are learnt in case-insensitive mode. Case-insensitive BPE model is very useful when dealing with noisy data (like, for example, OpenSubtitles where uppercase is often used to communicate emphasis) or legal and financial data where specific terms are written in title case or uppercase. News headlines are also often written in title case or uppercase.

The OpenNMT preprocessor handles case as a feature assigned to each token. As MarianNMT

[1] https://pypi.org/project/pycld2/
[2] https://pypi.org/project/langdetect/

does not support features yet, we perform a 'trick' similar to the one described in (Tamchyna et al., 2017): instead of using a feature we insert special tokens <C> and <U> after sequences in title case or uppercase. For example, a source sentence

World Championships 2017: Neil Black praises Scottish members of Team GB

is converted to

world <C> championships <C> 2017 : neil <C> black <C> pra@@ ises scottish <C> members of team <C> gb <U>

We do not use truecaser in our pipeline as it is redundant. All data is tokenized using the `Moses` toolkit (Koehn et al., 2007) tokenizer with aggressive tokenization, then the OpenNMT BPE-splitter is applied, after that we convert the case feature to separate tokens.

General tendency for our models this year is to build smaller BPE models.

English-Russian and Russian-English

Same as last year (Molchanov, 2019), we train the models with separate vocabularies due to the Cyrillic nature of Russian alphabet. Therefore we build separate BPE models for source and target, but with less merge operations (16k for English and 32k for Russian) compared to last year (35k and 45k respectively).

English-German and German-English

We train a joint BPE model for the English-German pair with 16k merge operations. We use a shared vocabulary and tie all embeddings for all translation models with joint BPE.

Polish-English

We train a joint BPE model for the Polish-English pair with 12k merge operations.

Czech-English

As was mentioned earlier, our Czech-English model is a multilingual model trained to translate from Czech, Croatian, Serbian and Slovak into English. Therefore we train a joint BPE model for all five languages with 24k merge operations. As part of Serbian data is in Cyrillic alphabet, we transliterate it into Latin using an inhouse transliteration tool.

3.3 Synthetic data

There are two types of additional synthetic training data described in detail below. The final size of the training data for the submitted systems is roughly 4 times the total size of the filtered data in Table 1 Table 1 for each language pair.

Both types of synthetic data are used for training all submitted systems. We also tag all synthetic data following (Caswell et al., 2019), i.e., insert a special token <*bt*> at the beginning of each source line for back-translations etc.

Back-translated data

Back-translations (Sennrich et al., 2016a) are a common way to improve NMT models quality. As we aim at building general-domain models, we use data from Wikipedia dumps and news from statmt.org. We shuffle the Wikipedia data and randomly select a subset of appropriate size. The selected Wikipedia subset and the news subset are roughly equal in size. The size of the whole corpus used for back-translation is approximately equivalent to the size of human training data.

For the English-Russian pair we use our last year's English-Russian model to obtain back-translations for the Russian-English model. Then we train the Russian-English model and use it to obtain back-translations for the final English-Russian model.

We also obtain back-translations for the German-English pair using our last year's models.

For the Polish-English and Czech-English pairs we build intermediate models using all available data excluding OpenSubtitles and Paracrawl.

We score our back-translations with the opposite-direction NMT models to discard obviously bad translations.

Replicated data with unknown words

We apply the technique described in (Pinnis et al., 2017) to create a synthetic parallel corpus. The procedure includes the following steps: first, we perform word-alignment of our initial parallel training corpus using the fast-align tool (Dyer et al., 2013). Then, we randomly replace from one to three unambiguously (one-to-one) aligned tokens in both source and target parallel sentences with the special <UNK> placeholder. The same pipeline is applied to both the initial and back-translated data. We train our models to reproduce the <UNK> placeholder in various contexts and

use this feature for handling named entities as described in Section 4.1 below.

3.4 Data for fine-tuning

We only do fine-tuning for the Czech-English system. The model is tuned on available parallel Czech-English data mixed with back-translations of the English news 2017-2019 from statmt.org. We use the newstest2017-2019 as our devset.

4 Systems architecture

This section describes the trained systems in detail. We train transformer (Vaswani et al., 2017) models for all submitted systems. We use the recipe available at the MarianNMT website[3]. The system configuration, hyperparameters and training steps follow those in the recipe.

We use the transformer-big configuration for the English-Russian model.

We train single models for all directions.

We use the beam of size 6 and the `--normalize` parameter is set to 0.6.

4.1 Handling named entities

We preserve several types of named entities (NEs): numbers, emails, alphanumeric sequencies etc. in the following way. First, we produce the baseline NMT translation without any processing. Then we validate the translation of NEs by comparing the system's output to the source sentence. The validation is simple: we search for the corresponding strings (numbers, emails etc.) in the system's output. If some of the NEs are not translated or are translated incorrectly, we replace the entities with the <UNK> placeholder in the source sentence and translate the sentence again allowing the decoder to generate unknown words in the output. Finally, we substitute the <UNK> placeholders in the output with their initial value. If the number of the <UNK> placeholders in the NMT system's output is not equal to the number of the placeholders in the source sentence, we fall back to the baseline NMT translation without NEs processing. We do not do any specific processing for proper names.

5 Results and discussion

In this section we present the BLEU (Papineni et al., 2002) scores for our systems on two test sets and the analysis of the results.

The scores are presented in Table 2. Calculation is done using the `multi-bleu-detok.perl` script from the `Moses` toolkit.

We significantly outperform our last year's submissions for the News Task.

Fine-tuning for the Czech-English system does not give us significant improvements in terms of BLEU. This may be because we didn't perform any data selection this year.

System	newstest2019	newstest2020
English-Russian		
Model2019	29.5	21.7
Model2020	**32.3**	**23.3**
Russian-English		
Model2019	37.2	33.6
Model2020	**42.3**	**38.2**
Polish-English		
Model2020	-	**31.3**
English-German		
Model2019	38.2	29.8
Model2020	**40.7**	**31.9**
German-English		
Model2019	32.4	34.9
Model2020	**39.4**	**39.6**
Czech-English		
Model2020	-	25.1
Model2020 tuned	-	**25.6**

Table 2: Results for different systems and directions. The submitted systems are marked in bold. Model2019 stands for our last year's submitted systems which we consider the baseline.

We are among the top 10 systems in the English<>Russian directions, however, we are substantially behind the top systems in other directions in terms of BLEU. We see two reasons for that. First of all, we pay much more attention to our Russian systems, thus, our last year's Russian systems had already undergone several iterations of updated backtranslations and retraining and can be considered strong baselines. Second, we possess much more private high-quality data for the English-Russian pair compared to other language pairs.

[3] https://github.com/marian-nmt/marian-examples/tree/master/wmt2017-transformer

6 Conclusions and Future work

In this paper we have described our submissions for the WMT 2020 Shared News Translation Task. Overall we have made six submissions in four language pairs: English-Russian, English-German, Polish-English and Czech-English.

We have documented the methodology used to prepare the training data, system training set-ups, the pipeline for handling NEs.

We show competitive results in most directions.

In future we plan to experiment once again with a shared vocabulary for the English-Russian models applying transliteration to the source side.

Abstract

The paper describes the submissions of the eTranslation team to the WMT 2020 news translation shared task. Leveraging the experience from the team's participation last year we developed systems for 5 language pairs with various strategies. Compared to last year, for some language pairs we dedicated a lot more resources to training, and tried to follow standard best practices to build competitive systems which can achieve good results in the rankings. By using deep and complex architectures we sacrificed direct re-usability of our systems in production environments but evaluation showed that this approach could result in better models that significantly outperform baseline architectures. We submitted two systems to the zero shot robustness task. These submissions are described briefly in this paper as well.

1 Introduction

The European Commission's eTranslation project[1], a building block of the Connecting Europe Facility (CEF), has been set up to help European and national public administrations exchange information across language barriers in the EU. More details about the project can be found in (Oravecz et al., 2019). Our participation in last year's WMT shared task marked an important step towards opening the service to the coverage of additional, non-EU languages and to domains beyond the formal language of EU institutions. Due to the encouragement and insights we received from WMT 2019, a complete set of general domain MT engines has meanwhile been implemented and incorporated into the eTranslation service.

This year the team participated in the news translation shared task with five different language pairs: English → German, Japanese → English, English → Polish, Russian → English and English → Czech. The varying performance of these systems reflects the amount of resources dedicated to their developments.

2 Data Preparation

This section briefly describes the data sets, the selection, and filtering methods applied to the provided parallel and monolingual data in order to increase the quality of trained models. We primarily focused on constrained submissions, but due to the low quality of our first En→Pl models trained only on the constrained data set we switched to the unconstrained scenario and chose to submit only the unconstrained En→Pl system (see Section 4.3).

2.1 Data Selection and Filtering

In general, we made use of all provided original parallel (OP) data to build baseline models for reference or back-translation. Some brief experiments were made with the exclusion of one or the other data set. However, the best baseline models were trained when we used all OP data (except for the UN Parallel Corpus for Ru→En, which, like last year, did not improve the results). This year, where we used it, we did not apply any advanced filtering technique to ParaCrawl (except for JParaCrawl for Ja→En) either, the 5.1 version proved to be usable without further complex processing.

The domain distribution of the data sets was not uniform across language pairs, which had some influence on the workflows we applied to specific language pairs but the basic procedure of data cleaning was similar in all cases.

As a general clean-up, we performed the following steps on the parallel data[2]:

- language identification with FastText[3] (Joulin et al., 2016),

[1] https://ec.europa.eu/cefdigital/wiki/display/CEFDIGITAL/eTranslation

[2] For Japanese, these steps were not used.

Table 1: Number of segments in the filtered parallel data used for baseline models.

- segment deduplication with masked numerals[4],
- deletion of segments where source/target token ratio exceeds 1:3 (or 3:1),
- deletion of segments longer than 100-150 tokens (depending on language pair),
- exclusion of segments without a minimum number of alphabetic characters.

The above steps led to an average reduction of about 10% of the training data.

We applied language specific filtering in Ja→En to exclude segments which contained non-Latin (Greek) or non-CJK character ranges, and in En→Cs we added a sentence segmentation step using Tikal[5] to break up a large number of raw segments merging several sentences. In the En→Pl and Ru→En data sets, we filtered out segments with more than 8 or mismatched numeric tokens, and deleted segments filled with excessive punctuation marks. The number of segments in the base filtered data is shown in Table 1.

In the language pairs where we used monolingual data to build language models or create synthetic parallel text, we generally selected recent target language News Crawl data sets. For En→Pl, the 1.32B segments of the Polish Common Crawl were ranked with a language model built on the News Crawl data, and the top 2.15M segments were used for back-translation. In the non-Japanese back-translation data we performed some additional filtering: we set a threshold on the maximum length of a token (40-100) and the minimum ratio of letters to digits in a segment (4), filtered out segments with scrambled tokens (2019 German News Crawl) or token (bigram) repetitions (En→Cs).

Depending on data availability we needed different ways of creating development and test data sets. For En→De and En→Cs, we used the 2018 test set as validation set in the trainings and the 2019 test set as the test set to evaluate the trained models. We did not specifically make a source original extraction from these data sets; the 2019 test set already contained only source original segments and the 2018 set was only used for early stopping of the training (see Section 3.2.2 for the use of source original data sets in the trainings).

For Ru→En, we used the 2018 and 2019 test sets for testing and 2500 segments randomly selected from the combined 2012-2017 test sets. For En→Pl, due to data sparsity, we used 500 segments of the 2020 dev set for testing and the rest for validation. For Ja→En, the provided development set was used to test the models during development, while a random subset of 3000 segments from OP was extracted to serve as validation set.

2.2 Pre- and Postprocessing

Similarly to our last year's submissions (Oravecz et al., 2019), in the default workflows, we generally did not apply the standard pre- and postprocessing steps of truecasing, or (de)tokenization, these

[4]We deleted duplicate segments regardless of differences in numerals.

[5]https://okapiframework.org/

did not have a noticeable effect on most of the results. We simply used SentencePiece (Kudo, 2018), which allows raw text input/output within the Marian toolkit (Junczys-Dowmunt et al., 2018)[6] in the experiments. For certain language pairs, however, some tailored processing steps were applied and tested. These are described in detail in the language pair specific result sections.

3 Trainings

Our access to computing resources is not unlimited. Therefore, we did not have much room for large scale experiments with either a wide range of scenarios or extensive tuning of hyperparameters. Nevertheless, as opposed to last year, where we decided to stick only to simple setups and training procedures, this year we tried more complex models and utilized significantly more data where it was possible. In all experiments we used Marian, which is the core tool of our standard NMT framework in the eTranslation service. All trainings were run as multi-GPU trainings on 2 or 4 NVIDIA V100 GPUs with 16GB RAM. Base transformers were typically trained for 7 epochs for high resource and 11 epochs for lower resource language pairs, whereas big transfomers were generally trained for 12 epochs for high and 30 epochs for lower resource.

3.1 NMT Models

We trained base transformer models (Vaswani et al., 2017) in all language pairs for the first baseline models and for models used for back-translation to gain efficiency in back-translating large amounts of target monolingual data. To build the more competitive systems we switched to big transformer architectures; this in some cases led to significant improvements but at the same time the rise in computing costs was also substantial. This year we also built 2–4 member ensembles from big transformers for high resource language pairs; again a high cost for a relatively smaller scale improvement. For most of the hyperparameters we used the default settings for the base transformer architecture in Marian[7] with dynamic batching and tying all embeddings. To save time and resources, we stopped the trainings if sentence-wise normalized cross-entropy on the validation set did not improve in 5 consecutive validation steps. In the big transformer experiments, following recommended settings for Marian, we doubled the filter size and the number of heads, decreased the learning rate from 0.0003 to 0.0002 and halved the update value for `--lr-warmup` and `--lr-decay-inv-sqrt`.

For En→De and En→Cs we set a 36k joint SentencePiece vocabulary, which seems to be more or less in the standard range nowadays. We had some previous experiments with other vocabulary sizes but with no improvement. Ja→En models were trained with a 32k vocabulary size, En→Pl with 32k, and Ru→En with 30k.

3.2 Improving Baseline Models

This section describes the methods we applied to improve baseline models, such as building additional synthetic data sets with back-translation (Sennrich et al., 2016), using original parallel or development data (where available) to continue the training of already converged models and building ensembles of deep models originally trained from different seeds. Evaluation scores are reported in Section 4.

3.2.1 Synthetic Data

Back-translation (BT) is a standard data augmentation technique in neural machine translation, but one which brings another set of tunable parameters in the search for best settings as far as the optimal amount of synthetic data, ratio of bitext to back-translation data or methods to generate the synthetic source are concerned (Edunov et al., 2018; Hoang et al., 2018). Tagged back-translation (Caswell et al., 2019) has recently been proposed as a simple alternative to noising techniques, arguing that it is the indication of the data being synthetic that is relevant for the model. This has been justified in our experiments as well, therefore we used this technique in all workflows for all language pairs.

In the En→De system, we ran various experiments with small amounts of BT data from the 2019 News Crawl (10M, 20M, 50M), which gave some improvement in the base architectures. However, for the deeper models we back-translated 116M[8] 2016, 2017 and 2019 News Crawl segments and used it as tagged synthetic data in the trainings (with segments longer than 75 tokens filtered

[6] We used default settings for Marian's built-in SentencePiece: unigram model, built-in normalization and no subword regularization.

[7] See eg. `https://github.com/marian-nmt/marian-examples/tree/master/transformer`.

[8] From 170M after the filtering.

out). As suggested by Ng et al. (2019) and Junczys-Dowmunt (2019), we upsampled the original parallel data to a 1:1 ratio.[9] This setup was a one shot configuration, we had no time and resources to experiment with using more BT data or other OP-BT combinations. In En→Cs we followed a similar procedure of back-translating recent News Crawl data and upsampling the OP data to keep the balance of the two types of data sets.

For Ja→En, we tried to use only News Crawl or use it together with the News Discussions monolingual data. Both setups gave similar results in the end. In Ru→En, we first experimented with the BT data provided by the University of Edinburgh but this was not beneficial so we decided to use only translations produced by our own BT systems. We translated 100M of the monolingual English data (50M News Crawl (2017-2019) and 50M News Discussions (2018–2019)), and filtered it down with LMs to 50.4M.

For En→Pl, we translated all of the available Polish News Crawl (3.79M) as well as 2.15M of the Polish Common Crawl (cf. Section 2.1). They were subsequently filtered down to 3.7M and 1.97M.

3.2.2 Continued Trainings

This year we experimented with a two stage continued training process as a possible direction to improve performance as domain adaptation (Luong and Manning, 2015). For En→De, we built a transformer language model from the 2016, 2017 and 2019 filtered News Crawl data set (116M segments) and scored the German side of the original parallel data. The scores created a ranking of OP data from which we took the top 20M[10] to continue training of OP+BT trained models (as suggested by Junczys-Dowmunt (2019)) until the BLEU score on the test set increased (typically 2 epochs with an increase of 1 point). In the second stage, we used the 2008–2018 development sets (32.5k segments) in the experiments and for the final submission we extended it with the 2019 test set. We trained 4 epochs on this set and then for additional 2 epochs we switched to a source original subset (14.5k) to reach the highest BLEU score. This second stage yielded a much smaller improvement than last year. However, this year the starting models were more powerful already. Fine tuning on the development set worked much better for Ja→En, where we achieved more than 2 points BLEU score (Table 3) increase on the best performing engine by continuing the training until the first stall (20 epochs). The same procedure, however, did not give any improvement for En→Cs.

3.2.3 Ensembles

For the En→De final submissions, we set up a 4 big transformer ensemble trained with the same (best) configuration and workflow but with different seeds. As reported in Section 4.1, this system achieved the highest score and was submitted as primary. In Ja→En, a two model ensemble did not yield any improvement so it was not submitted, in En→Cs, a two model ensemble was submitted because it outperformed a three model one on the development set. The Ru→En and the En→Pl systems submitted were 3 model big transformer ensembles the latter with only a minimal increase in performance compared to the single models (cf. Section 4.3).

3.2.4 Ineffective Methods

We make a brief mention of the methods that we tried but did not lead to any increase in quality. In particular, for En→De, we built two big R2L models for rescoring ensemble outputs but this technique did not yield any improvement. Therefore, we stopped the experiments in this direction. We also tried to improve the performance of the final ensemble by adding a transformer type language model trained for 2 epochs from the same German News Crawl data we used in other components (116M segments), but this setup did not help in any weight combination we tested either.

In Ja→En, we tested various preprocessing workflows including NFKC Unicode normalization, replacing numbers with placeholders, and also experimented with data selection using only subsets of monolingual data (without News Discussions), subsets of News Commentary selected by topic modelling and n-gram or transformer LM based data selection for tuning, all with no improvement in the results.

4 Results

We submitted one system for each of the five language pairs. In this section we provide evaluation scores for models at important stages in the experiments, which reflect how the models got better

[9] For En→De this meant taking the full OP dataset twice and padding the rest with a subset of OP. This subset was from a language model scored OP data set, see Section 3.2.2 for more details.

[10] We tried 10M and the full 44.7M sets as well.

as we tried various methods for improvement. All results are reported in detokenized BLEU.[11]

4.1 English→German

System	Data	Test sets 2019	2020
M1: Baseline	44.7M	41.9	32.7
M2: M1+BT+CT	64.7M	43.3	34.4
M3: M2+Tbig	232M	44.5	36.9
M4: M3+FT	232M+34.5k	44.8	37.2
M5: M4 ens	232M+34.5k	**46.0**	**37.9**

Table 2: Results for En→De models. The 2020 results are post-submission with the updated (A) reference set.

In Table 2 we present the main stages of the development of the En→De systems. Model 1 was our baseline model and used only the original parallel data[12] (Table 1), which was almost eight times more (already including the full ParaCrawl) than last year, and so the result on the 2019 test set already equaled the performance of our best submission model from last year (Oravecz et al., 2019). Model 2 was the best single base transformer trained from OP extended with 20M tagged back-translated (BT) segments and then with continued training (CT) on the language model scored 20M OP data subset. This yielded substantial improvement but was still far from the best setups. For Model 3, we switched to the big transformer architecture and used the large BT dataset (116M) with the upsampled OP. The training procedure was the same as in the previous system; the first converged model was trained further with the LM-scored OP subset as long as the BLEU score increased. Clearly, this resulted in a more powerful system, further improving the result. The next model (M4) was fine-tuned (FT) with the development set, bringing a small but steady increase. Finally the system we submitted was an ensemble of four M4 models. As last year, a postprocessing step normalizing German punctuation was run on the final hypotheses.

This year the development of the best performing En→De system was dominated by brute force: the more complex and resource demanding architectures performed significantly better, although some careful selection and ranking of the training data also played a role. We managed to train better and better systems as we added more and more resources, and it is very likely that without the limitations in our training environment results could have been further improved.

4.2 Japanese→English

System	Property	Score	Increment
M1	baseline	20.42	–
M2	Bicl. filtering	21.35	+0.93
M3	Unicode filtering	21.53	+0.18
M4	normalization	22.13	+0.60
M5	truecasing	22.07	-0.06
M6	back-translation	23.48	+1.35
M7	balanced BT	23.73	+0.25
M8	fixed big numbers	23.97	+0.24
M9	big transformer	25.39	+1.42
M10	tuned with devset	**27.58**	+2.19

Table 3: Results for Ja→En models. The BLEU score is measured on the development set.

Table 3 summarizes the results of the Ja→En experiments. We trained more than 20 different models from which we present those that produce some increment in the BLEU score. The M1 baseline model was trained from the original parallel data, 13.4 million segments from the 7 constrained resources. This baseline already contained some minimal filtering of duplicates, deletion of markup etc. The M2 model was filtered with Bicleaner (Sánchez-Cartagena et al., 2018), where the filter model was built from this training data. In the M3 system, we used a Unicode range filter, leaving segments containing text using characters only from 35 Unicode character ranges out of the possible 150. In the M4 model, this Unicode filtering was applied before building the Bicleaner filter model. The M5 model used truecasing on the English training and translation data. In M6, synthetic data from back-translation of the monolingual English News Crawl (33M), News Discussion (30M) and News Commentary (0.6M) was added (and tagged). The M7 model contains the same data but the original parallel data was upsampled 3 times to keep a 1:1 ratio to the back-translated data. In M8, we normalized big Japanese numbers to match with

[11] sacreBLEU signatures: `BLEU+case.mixed+lang.en-de+numrefs.1+smooth.exp+tok.13a+version.1.4.12`

[12] We trained only with unique segments, this accounts for the 1.7M decrease from the 46.43M in Table 1.

millions and billions, which were frequently used in the news domain. M9 was a big transformer model built on 4 V100 GPUs. In model M10 (submitted), we tuned the big transformer model on the development set.

4.3 English→Polish

System	Data	Test sets 2020d	2020
M1: Baseline	8.00M	22.2	22.5
M2: M1+BTnews	11.0M	23.3	22.8
M3: M2+BT-Comm-Cr	13.0M	23.4	23.0
Unconstrained			
M4: M3+OPUS+news	53.1M	24.2	23.8
M5: M4+Tbig	53.1M	26.0	24.9
M6: M5 ens	53.1M	26.0	25.0
M7: M6+FT	53.1M	–	**27.2**

Table 4: Results for En→Pl models. The 2020 results are post-submission.

Table 4 presents the main stages of the development of the En→Pl systems. Model 1 was a base Transformer and used only the original parallel data (Table 1). Model 2 included the back-translated News Crawl data, and Model 3 had the addition of the back-translated Common Crawl subset. Each step gave only a very modest improvement. At this stage, we tried to make use of additional data sets and switched to experimenting with unconstrained systems. For Model 4, we added 40M segments of filtered OPUS parallel data, and a small amount of monolingual Polish proprietary data that was back-translated into English. Model 5 is similar to M4 but it is a big transformer, and Model 6 is an ensemble built of three M5 models trained from different seeds. All models for the ensemble were fine-tuned for 24 epochs on 5.5k of domain-specific data consisting of a thousand sentences from the development set plus the manually selected back-translated proprietary news data.

4.4 Russian→English

Table 5 gives a summary of the development stages of the Ru→En systems. M1 and M2 are our baseline systems. Initially, the WikiMatrix data (WM) for Russian was corrupt and we built a baseline without it. After a usable version was provided, we trained another baseline system. M3 included some

System	Data	Test sets 2019	2020
M1: Baseline	6.40M	37.3	33.7
M2: M1+WM	9.80M	38.9	35.3
M3: M2+BT	98.5M	39.1	37.2
M4: M3+Tbig ens	98.5M	40.1	38.0
M5: M3+Tbig+FT1	98.5M	39.6	36.6
M6: M3 ens+FT2	98.5M	–	**37.5**

Table 5: Results for Ru→En models. The 2020 results are post-submission.

50M of back-translated News Crawl and News Discussions data and the OP data of M2 upscaled to a 1:1 ratio to the back-translated data. M4 is an ensemble of 3 big transformer models trained with the same workflow as M3 but with different seeds. M5 is a single big transformer (one of the three in M4) that was fine-tuned for 6 epochs on the 2012–2018 development sets. Finally, M6 is a 3 model ensemble of the fine-tuned models from M4, but for submission fine-tuned on the 2012–2019 development sets.

4.5 English→Czech

System	Parallel data	Test sets 2019	2020
M1: Baseline	45.0M	26.5	31.4
M2: M1+BT	166M	26.8	32.2
M3: M2+Tbig	166M	28.3	33.8
M4: M2+Tbig	166M	28.6	33.7
M5: M3+M4 ens	166M	**28.9**	34.4
M6: sent. seg.	166M	–	**35.7**

Table 6: Results for En→Cs models. The 2020 results are post-submission.

We trained only a few straightforward models for the En→Cs system. The scores in Table 6 give the outcome of the evaluation of 6 simple setups: Model 1 was a base transformer built on the original parallel data (excluding ParaCrawl, which decreased the score). The data for Model 2 was extended with back-translated 2007-2019 News Crawl. In various experiments, the pre 2019 News Crawl data only gave a minor increase in BLEU, the 2019 set was more useful. For the other models, we trained big transformers and built small

ensembles. However, an ensemble of two outperformed the ensemble of three models in the end. We tried continued training on the development sets from the previous years, but it only led to a drop in the score. As a basic post-processing step, we applied double quote and ellipsis normalization. The 2020 test set contained segments with multiple sentences, so in the submission set we performed some sentence segmentation in preprocessing before translation.

4.6 Zero Shot Submissions to the Robustness Task

The best performing En→De (fine-tuned 4 member big transformer ensemble) and Ja→En (fine-tuned big transformer) systems were submitted without any changes as zero shot models for the Robustness Task. Interestingly, these zero shot models (as well as most of the submissions from the other participants), seemed to score better on these very noisy test sets than on the news test sets, suggesting that the training data used was not completely news domain oriented and might already give good support for diverse domains.

5 Conclusion

We described the submissions of the eTranslation team to the WMT 2020 news translation shared task on 5 language pairs: English-German, Japanese-English, English-Polish, Russian-English, and English-Czech. Like last year, we tried to build the best possible systems in a relatively low-resource production environment. But in contrast to last year, we dedicated more resources to certain language pairs, and tried more complex models and utilized significantly more data where possible. In particular, we experimented with various techniques (big transformer models, synthetic data obtained from tagged back-translation, two stage continued training process, ensembling up to 4 models) and obtained significant improvements over baseline models: from 4 to 7 BLEU points depending on the language pair on the 2020 test sets. We ranked competitively in all language pairs, reducing the gap from the best systems significantly from last year.[13] However, the submitted setups cannot be reused in our production environment due to their excessive demands on resources, but lessons learnt from those experiments shall provide valuable insights to improve the eTranslation system under its current constraints.[14]

For the production eTranslation service, with language specific systems for all official EU and EEA languages, finding the right balance between the use of resources in production environments and the best possible performance of models remains a challenge for future work.

[13] For example, in En→De from 3 BLEU points to 0.9.

[14] Current eTranslation resource capacity generally allows only for the baseline models to be trained and deployed, and this, although in a different domain from news, definitely leaves some room for simple "brute force" improvement of the service.

Abstract

This paper describes the ADAPT Centre's submissions to the WMT20 News translation shared task for English-to-Tamil and Tamil-to-English. We present our machine translation (MT) systems that were built using the state-of-the-art neural MT (NMT) model, Transformer. We applied various strategies in order to improve our baseline MT systems, e.g. monolingual sentence selection for creating synthetic training data, mining monolingual sentences for adapting our MT systems to the task, hyperparameters search for Transformer in low-resource scenarios. Our experiments show that adding the aforementioned techniques to the baseline yields an excellent performance in the English-to-Tamil and Tamil-to-English translation tasks.

1 Introduction

The ADAPT Centre participated in the News Translation Shared Task of the Fifth Conference of Machine Translation (WMT20) in the English-to-Tamil and Tamil-to-English language directions. To build our neural MT systems we used the Transformer model (Vaswani et al., 2017). Our strategies to build the competitive MT systems for the task include applying the state-of-the-art data augmentation approaches (e.g. (Sennrich et al., 2016a; Caswell et al., 2019)), selecting "pseudo" in-domain monolingual sentences for the creation of synthetic bitexts, mining monolingual source and target sentences for the adaptation of neural MT (NMT) systems, finding the optimal set of hyperparameters for Transformer as far as low-resource translation is concerned.

The remainder of the paper is organized as follows. In Section 2, we present our approaches for the MT system building. Section 3 first presents details of the data sets used and then presents the evaluation results with some discussions, while Section 4 concludes our work with avenues for future work.

2 Our Strategies to improve MT Systems

2.1 Data Augmentation

The data augmentation methods (Sennrich et al., 2016a; Zhang and Zong, 2016; Burlot and Yvon, 2018; Poncelas et al., 2018; Bogoychev and Sennrich, 2019; Caswell et al., 2019; Chen et al., 2019), which usually employ the unlabeled monolingual data in addition to limited bitexts, can positively impact the MT system's performance and are very popular among the MT developers and researchers (Barrault et al., 2019). In other words, use of augmented bitexts that include synthetic data to improve a NMT system is nowadays a common practice, especially in the under-resource scenarios. The synthetic training data whose target-side sentences are original is more effective for domain text translation and generation of fluent translations. In this task, in order to improve our baseline Transformer models, we augmented our training data with the target-original synthetic data. As in Caswell et al. (2019), in order to let the NMT model know that the given source is synthetic, we tag the back-translated source sentences with an extra token.

Note that we also tried applying the so-called self-training[1] strategy (Ueffing et al., 2007) to improve our NMT systems. However, this method does not bring any improvements in the Tamil-to-English translation task, and deteriorates the performance of the MT systems in the English-to-Tamil translation task.

Iterative generation and training on synthetic data can yield increasingly better NMT systems,

[1]Synthetic data for training is created by the MT system itself (i.e. source-side is original) (Zhang and Zong, 2016; Burlot and Yvon, 2018).

Proceedings of the 5th Conference on Machine Translation (WMT), pages 262–268
Online, November 19–20, 2020.

especially in low-resource scenarios (Hoang et al., 2018; Chen et al., 2019). Similarly, in order to produce our final English-to-Tamil and Tamil-to-English MT systems, we performed iterative training by back-translating new monolingual data with the updated MT system and appending the resultant synthetic data to the original training data in each iteration.

2.2 Selecting pseudo In-Domain Sentences

In an attempt to improve the quality of our NMT engines, we extracted monolingual sentences from large monolingual data that are similar to the styles of the in-domain data. Sentences of a large monolingual corpus similar to the in-domain sentences when selected based on the perplexity according to an in-domain language model were found to be effective in MT (Gao et al., 2002; Yasuda et al., 2008; Foster et al., 2010; Axelrod et al., 2011; Toral, 2013). As for NMT training, we believe that synthetic parallel data created using pseudo in-domain sentences can be better alternatives than those selected randomly. Accordingly, we select "pseudo" in-domain sentences from a large monolingual corpus based on the perplexity scores according to the in-domain language models. The extracted sentences are then back-translated with a target-to-source MT system to form synthetic training data.

2.3 Mining Monolingual Sentences for the Adaptation of the NMT models

Chinea-Ríos et al. (2017) demonstrated that in case of specialised domains or low-resource scenarios where parallel corpora are scarce sentences of a large monolingual data that are more related to the test set sentences to be translated could be effective for fine-tuning the original general domain NMT model. They select those instances from large monolingual corpus whose vector-space representation is similar to the representation of the test set instances. The selected sentences are then automatically translated by an NMT system that is trained on a general domain data. Finally, the NMT system is fine-tuned with the resultant synthetic data. In a similar line of research, it has also been shown that an NMT system built on general domain data can be fine-tuned using just a few sentences (Farajian et al., 2017, 2018; Wuebker et al., 2018; Huck et al., 2019).

In our case, since English–Tamil is a low-resource language-pair and have a little amount of bitexts pertaining to the targeted domain (News), we followed Chinea-Ríos et al. (2017) and mined those sentences from large monolingual data that can be beneficial for fine-tuning the original NMT models. In addition to mining source-side sentences (Chinea-Ríos et al., 2017), we also mined target language sentences from large monolingual corpus (Huck et al., 2019) when English is the source language. However, our selection methods are different to those of the other papers (Chinea-Ríos et al., 2017; Farajian et al., 2017, 2018; Wuebker et al., 2018; Huck et al., 2019) and are described below.

Terms are usually indicators of the nature of a domain and play a critical role in domain-specific MT (Haque et al., 2020). The target translation could lose its meaning if the terminology translation is not dealt with care. Therefore, we focused on mining those sentences from a large monolingual corpus that contain domain terms. For this, we made use the approach of Rayson and Garside (2000); Haque et al. (2014, 2018) for identifying terms in the test set which is to be translated. This term extraction method performs well even on a small amount of sentences (Haque et al., 2014, 2018). The goal is to identify those words which are most indicative (or characteristic) of the test corpus compared to a reference corpus. Haque et al. (2014, 2018) used a large corpus which is generic in nature as a reference corpus. We adopted their approach and used a large generic corpus in order to identify terms in the test set. Additionally, in our second setup, we used the training set on which the NMT systems were trained as the reference corpus. The intuition is to extract those terms or sequence of words from the test set that do not occur or rarely occur in the training set and convey representativeness of the test set. We merged the two sets of terms extracted following the two setups above. Given the resultant list of terms, we mine sentences from monolingual corpus.

We observed that the WMT20 News development text contains many named entities (NEs) and many of them are out-of-vocabulary items. We also found that our initial MT systems miserably failed to translate many NEs. Therefore, we used Stanford named entity recogniser (NER)[2] (Finkel et al., 2005) in order to identify NEs in the English test set. As above, we used the extracted NEs in order to mine sentences from a large monolingual corpus.

[2]https://nlp.stanford.edu/software/CRF-NER.html

We build an English-to-Tamil transliteration system and the extracted English NEs were transliterated into Tamil. Note that we took 5-best Tamil translations for an English NE as in Huck et al. (2019). These Tamil NEs were then used to mine Tamil sentences from a large target monolingual corpus.

In order to build the English-to-Tamil transliteration system, we used the 2016 Named Entity Transliteration Shared Task (NEWS) dataset[3] (Duan et al., 2016). We used our in-house machine transliteration tool (Haque et al., 2009) in order to prepare the English-to-Tamil transliteration system.

We could not apply this strategy in the Tamil-to-English translation task since there is no publicly available NER for Tamil. The source and target sentences that have been mined are translated with the final source-to-target and target-to-source NMT systems, respectively. This results in a set of synthetic sentence-pairs. Source sentences whose target-side is original are tagged with a special token (Caswell et al., 2019) (cf. Section 2.1). As in Chinea-Ríos et al. (2017), the original MT system is finally fine-tuned on these synthetic segment-pairs.

For mining monolingual sentences we create an efficient Trie structure given the large monolingual data. The idea is to store indices of the sentences (i.e. we restrict this number to 50) for each n-gram (upto trigram) of the corpus. Given the domain terms of the in-domain text, we can instantly retrieve the sentences from corpus.

2.4 Tuning Hyperparameters for Transformer

The NMT systems are Transformer models (Vaswani et al., 2017). To build our NMT systems, we used the MarianNMT (Junczys-Dowmunt et al., 2018) toolkit. The tokens of the training, evaluation and validation sets are segmented into sub-word units using Byte-Pair Encoding (BPE) (Sennrich et al., 2016b). Since English and Tamil are written in their own scripts and have no overlapping characters, BPE is applied individually on the source and target languages. Recently, Sennrich and Zhang (2019) demonstrated that commonly used hyper-parameter configuration do not lead to the best results in low-resource settings. Accordingly, we carried out a series of experiments in order to find the best hyperparameter configuration for Transformer in our low-resource setting.[4] In particular, we played with some of the hyperparameters, and found that the following configuration lead to the best results in our low-resource translation settings: (i) the BPE vocabulary size: 8,000, (ii) the sizes of the encoder and decoder layers: 4 and 6, respectively, (iii) learning-rate: 0.0005, (iv) dropout (Gal and Ghahramani, 2016) between layers: 0.1. As for the remaining hyperparameters, we followed the recommended best setup from Vaswani et al. (2017). The models are trained with the Adam optimizer (Kingma and Ba, 2014), reshuffling the training corpora for each epoch. The early stopping criteria is based on cross-entropy; however, the final NMT system is selected as per the highest BLEU score on the validation set. The beam size for search is set to 12. We make our final NMT model with ensembles of 8 models that are sampled from the training run.

3 Experiments and Results

3.1 Data sets

This section presents the data sets that were used for system building. We used the monolingual and bilingual data provided by the WMT20 task organisers only. No external data has been used for the MT system building. Table 1 presents the corpus statistics. The parallel corpora released by

	Parallel Data		
	sentences	words (EN)	words (TA)
train	350,142	6,489,872	5,763,047
test	1,000	23,259	17,966
dev.	989	23,415	17,901
	Monolingual Data		
English	17M	Tamil	31M

Table 1: The data statistics.

WMT20 for the English–Tamil task are from different sources (e.g. Tanzil v1[5] (Tiedemann, 2012), WikiMatrix[6] (Schwenk et al., 2019) and PMIndia[7] (Haddow and Kirefu, 2020)). We merged segment-pairs of all data sources, and after applying standard cleaning scripts to the data we are left with

[3] http://workshop.colips.org/news2016

[4] This set of experiments were conducted on English-to-Tamil only and using the bitexts only. The best hyperparameter setup found in this task is used in the reverse translation task.

[5] http://opus.nlpl.eu/Tanzil-v1.php

[6] https://ai.facebook.com/blog/wikimatrix/

[7] http://data.statmt.org/pmindia

350K parallel segments (cf. row 3 of Table 1). As for the monolingual data, we used News-Crawl[8] and CommonCrawl[9] corpora (cf. last row of Table 1).

We observed that the corpora of one language (say, Tamil) contains sentences of other languages (e.g. English), so we use a language identifier[10] in order to remove such noise. In order to perform tokenisation for English and Tamil texts, we used the standard tool[11] in the Moses toolkit.

WMT20 released a development set of 1,989 sentences (*newsdev2020*) whose domain is naturally news. We used 1,000 sentences from *newsdev2020* as test set, and we call the test set *newstest1k*. The remaining sentences (989) are treated as the validation set.

3.2 The Baseline MT Systems

The BLUE scores of the NMT systems trained on the authentic parallel corpus (cf. Table 1) are reported in Table 2. These BLEU scores represent the MT systems that were trained following the best hyperparameter settings described in Section 2.4. Note that these MT systems serve our baselines. We refer the baseline MT system as Base. We see from Table 2 that the English-to-Tamil and

	newstest1k
English-to-Tamil	5.81
Tamil-to-English	12.20

Table 2: The BLEU score of the baseline MT systems.

Tamil-to-English MT systems produce 5.81 and 12.20 BLEU scores, respectively, on the respective test sets. As expected, the translation quality from the morphologically-rich to morphologically-poor language improves.

3.3 The Improved MT Systems

We applied the pseudo in-domain sentence selection strategy described in Section 2.2 to the monolingual corpora (cf. Table 1), and considered the top-scored sentences for back-translation. Note that the in-domain language models for sentence selection were built on the PMI data whose domain is news in nature. The development set sentences (998 sentences; cf. Table 2) were also appended to the PMI data. The BLEU scores on the MT systems trained on the augmented training data are presented in Table 3. We stopped the iterative training process (cf. Section 2.1) when there were no significant improvements in terms of the test set BLEU scores. This training process provides us with the improved MT systems. As can be seen from Table 3, the final MT systems surpass the respective baseline MT systems with large margins.

	newstest1k BLEU	newstest2020 SacreBLEU
English-to-Tamil		
Base+ 800K	8.12	
Base+ 1.5M	9.35	
Base+ 2.7M	9.45	5.4
Tamil-to-English		
Base + 800K	18.33	
Base + 1.5M	18.52	
Base + 2.7M	19.41	
Base + 3.3M	19.91	14.7

Table 3: The BLEU scores of the MT systems trained on the interactively augmented training data.

We translate the blind test sets (newstest2020) for the English-to-Tamil and Tamil-to-English translation tasks released by WMT20 by the best MT systems (cf. Table 3). The blind test sets for the English-to-Tamil and Tamil-to-English tasks contain 6,988 and 997 segments, respectively. The sacreBLEU (Post, 2018) scores of the best NMT systems on newstest2020 are shown in the last column of Table 3.[12]

3.4 Fine-tuning the best NMT systems

This section presents the MT systems that were prepared by the adaptation technique described in Section 2.3. We mine the source and target monolingual sentences from the large monolingual corpora given the terms and NEs (and transliterated NEs) extracted from newstest1k.[13] As described in Section 2.3, synthetic data is created by translating the source and target sentences by the target-to-source and source-to-target MT systems (cf. Table 3; the best MT systems), respectively. Finally, the

[8] http://data.statmt.org/news-crawl

[12] The SacreBLEU scores were taken from OCELoT https://ocelot.mteval.org

[13] Note that NEs were extracted from the English text only.

best MT system is fine-tuned on the synthetic data. The BLEU scores of the adapted MT systems on newstest1k are reported in Section 4. When we compare the original MT systems reported in Table 3 with the adapted MT systems, we see that (i) the English-to-Tamil adapted MT system produces a 1.55 BLEU points (corresponding to 16.4% relative) improvement over the the original English-to-Tamil MT system, and (ii) the Tamil-to-English adapted MT system produces a 1.41 BLEU points (corresponding to 7.08% relative) improvement over the the original Tamil-to-English MT system. The improvements are statistically significant.

	newstest1k BLEU	newstest2020 SacreBLEU
English-to-Tamil	10.80	6.1
Tamil-to-English	21.32	15.8

Table 4: The BLEU and SacreBLEU scores of the adapted MT systems on newstest1k and newstest2020, respectively.

As above, we create the English-to-Tamil and Tamil-to-English adapted MT systems for the blind test sets. Then, we translate the blind test sets with the adapted MT systems. The sacreBLEU (Post, 2018) scores of the adapted MT systems on newstest2020 are shown in the last column of Table 4. Again, the adaption strategy brings about moderate improvements over the original MT systems, i.e. a 0.7 SacreBLEU points (corresponding to 13% relative) improvement for the English-to-Tamil translation and a 1.1 SacreBLEU points (corresponding to 7.5% relative) improvement for the Tamil-to-English translation.

4 Conclusion

This paper presents the ADAPT system description for the WMT20 News Translation Shared Task. We participated in the English-to-Tamil and Tamil-to-English tasks. English–Tamil is a low-resource language-pair and we used the data provided by the WMT20 organisers only. Given the limited resources provided for the tasks, we aimed to build the competitive translation systems for the competition. For this, we applied a variety of strategies, e.g. iterative data augmentation, selection of pseudo in-domain sentences, and a novel strategy for the adaptation of the NMT models to the task. We found that the systematic addition of these techniques to baseline yields excellent improvements over the baseline.

This paper presented an effective adaptation method for the NMT systems. This method is found to be effective as far as the translation task we participated in is concerned. In the future, we aim to test on-the-fly adaptation method (Farajian et al., 2017, 2018) to translate domain texts.

CUNI English-Czech and English-Polish Systems in WMT20: Robust Document-Level Training

Martin Popel
Charles University, Faculty of Mathematics and Physics,
Institute of Formal and Applied Linguistics,
Malostranské náměstí 25, 118 00 Prague, Czech Republic
popel@ufal.mff.cuni.cz

Abstract

We describe our two NMT systems submitted to the WMT 2020 shared task in English↔Czech and English↔Polish news translation. One system is sentence level, translating each sentence independently. The second system is document level, translating multiple sentences, trained on multi-sentence sequences up to 3000 characters long.

1 Introduction

In this paper, we describe our two NMT systems submitted to the WMT 2020 news translation shared task: "CUNI-Transformer" (Charles University Transformer, sentence-level) and "CUNI-DocTransformer" (document-level). We trained them for English↔Czech and the former one also for English↔Polish (no parallel document-level data was provided for English-Polish, thus we could not train the latter one).

2 Common settings

Both our systems are implemented in the Tensor2Tensor framework (Vaswani et al., 2018) and have the same Transformer (Vaswani et al., 2017) architecture – transformer_big with 12 encoder layers instead of the default 6 (while keeping 6 layers in the decoder). The 32k joint English-Czech subword vocabulary is exactly the same as used by Popel (2018) and Popel et al. (2019), which are the systems we submitted to WMT in the last two years. Also most of the hyperparameters (except for the encoder depth) and the training regime are the same.

The main improvement of our sentence-level system relative to our last-year submission stems from using slightly larger and better-filtered training data – CzEng 2.0 (Kocmi et al., 2020b) with 61M authentic parallel and 127M synthetic (back-translated) sentences (see Table 1), instead of CzEng 1.7 with 57M authentic parallel sentences.

data set	sentence pairs (M)	words (M) EN	CS
authentic	61	617	702
EN-mono (NewsCrawl 2016–2018)	76	1296	1474
CS-mono (NewsCrawl 2013–2018)	51	700	833
total	188	2613	3009

Table 1: Training data sizes (in millions). All the data are taken from CzEng 2.0.

We also enlarged our development-test set: we concatenated WMT newstest 2008–2018, instead of using newstest2016 only. WMT news tests before 2020 did not have paragraph boundaries marked. We thus prepared a version of our dev-set where we joined together several consecutive sentences randomly (except for titles not ended by a punctuation) to simulate WMT2020 paragraph-level setting.

Our document-level system was further improved as described in Sections 3 and 4.

3 Document-level training

Our last-year document-level submission (Popel et al., 2019) introduced a method of training-data context augmentation, where multiple consecutive sentences (within original documents) are merged together into multi-sentence sequences (of parallel source-target data). The sentences within each sequence are separated with a special token, so that we can easily extract the sentence alignment after decoding. The length of the sequences was limited by 1000 characters and 200 subwords (i.e. any sequences longer than any of the limits in either source or target were discarded from training).

An important aspect of this method is that it extracts all possible sequences from the document-level training data. For example, given a document

Proceedings of the 5th Conference on Machine Translation (WMT), pages 269–273
Online, November 19–20, 2020.

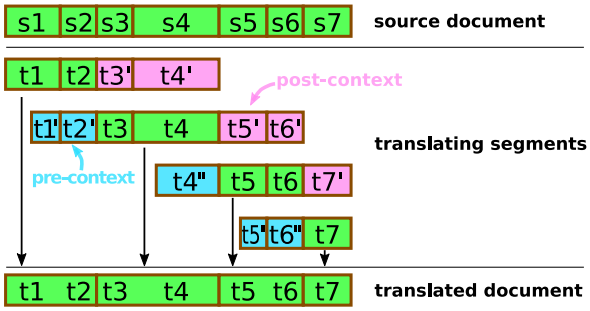

Figure 1: Decoding overlapping multi-sentence sequences with our document-level model. Note that the pre-context part may start not only on sentence boundaries (it improves the results slightly according our initial experiments).

with 5 sentences s1–s5, we extract sequences s1, s1–2, s1–s3, s2, s2–s3, s2–s4, s3, s3–s4, s3–s5, s4, s4–s5 and s5, while ignoring sequences s1–s4, s1–s5 and s2–s5 because these are longer than the limits. Note that this way of context augmentation implicitly upsamples sentences from longer documents relative to sentences from shorter documents. A sentence appearing in N windows of at most 1000 characters is present N times in the augmented training data.

Thus this year, we simply sample non-overlapping sequences of sentences: s1–s3, s4–s5. There are many documents shorter than the limits in CzEng 2.0, including many single-sentence documents (from sources without document-level annotation). Thus, there are naturally occurring trainng sequences which are shorter than the limits and we checked the model is capable of translating also single sentences.

In addition to this change in data sampling, we increased the sequence length limit to 3000 characters and 750 subwords.

4 Document-level decoding

There are many possible ways how to use document-level models (trained as described in the previous section) at decode time.

- We can translate single sentences, thus not using the advantage of document-level training. This may serve as a baseline for comparison with document-level decoding and we used this for our last-year sentence-level submission "Transformer T2T 2019" (Popel et al., 2019).

- We can split each input document into non-overlapping multi-sentence sequences.

- We can split each input document into overlapping multi-sentence sequences (with so-called pre-context and post-context parts, which are ignored in the final translation) as suggested by Popel et al. (2019) and explained in Figure 1.

- We can use the overlapping sequences for some kind of consensus decoding or ensembling. We have not tried this option yet.

Because of the increased limits of training sequences, we increased also the decoding limits two times: pre-context of up to 400 characters, main content of up to 1000 characters and post-context of up to 1800 characters minus the length of the pre-context and main content.

5 Robust training with noising

To make the model more robust to real-world user-generated data, we added a noise to the training data. We followed an approach of Náplava and Straka (2019) and made the source side of the training data more noisy by introducing both grammatical and spelling errors. The basic set of noising operations introducing grammatical errors consisted of the following operations: token replacement with one of its spelling dictionary proposals, token deletion and insertion and swapping of two nearby words. Moreover, we also allowed to replace phrases with one of their most frequent variants, add or delete punctuation and allowed to strip diacritics.

We applied this technique only to our Czech→English sentence-level system by noising the source=Czech side of both the authentic and synthetic parallel data. In preliminary experiments, we observed substantial improvements on artificially noised dev sets, but slight worsenings on WMT dev sets, which contain just a very small amount of typos and other errors (on the source side). We thus decided to mix the noised training data with the original unnoised data 1:1. This resulted in approximately the same BLEU on the original dev sets as without noising, while keeping the improved results on artificially noised dev sets.

For time constraints, we decided to not use any noising in the document-level Czech→English training, as well as in our English→Czech and English↔Polish systems.

6 Results

In Tables 2–5, we report BLEU scores on the newstest2020 for all the systems submitted to WMT.[1] For English→Czech and English→Polish (Tables 2 and 4), we report also gender coreference accuracy scores based on WinoMT testset results (Kocmi et al., 2020a). For English→Czech, we report also manual document-level quality evaluation by Zouhar et al. (2020) of 269 WMT2020 test-suites sentences (i.e. not sentences from newstest2020). The official manual evaluation on newstest2020 is not available yet.

We can see that while our DocTransformer was not the best system according to BLEU, it scored well according to the other two reported metrics, being the best system in English→Czech and the second-best in English→Polish. This could be caused by the low reliability of BLEU (and other metrics based on similarity with reference) for high-quality MT, or by the domain mismatch – the test-suites contain also other domains than news. Unfortunatelly, we cannot answer this question before further analysis using the official WMT manual evaluation, once it is done and published.

Finally, we present several translation examples in the Appendix. The source English documents were taken from the WMT2019 newstest and the same examples were selected already by Popel et al. (2019). Table 6 shows three examples where the document-level model corrects a lexical error of our 2019 sentence-level model. Interestingly, two of these errors were fixed also by our this-year sentence-level model, showing that the cross-sentence context is not *necessary* for correct translation of these examples. Table 7 shows an error of our 2019 document-level model, which is not present in this-year models.

7 Conclusion

We suceeded to improve our baseline system CUNI-T2T-2018 (Popel et al., 2019) by using better training data, doubling the encoder depth (to 12 layers) and by robust training with source-side noising. While all these three techniques are well-known, we show improvements in improving the last-year WMT state of the art in English-Czech translation. We improved also our document-level system (CUNI-DocTransformer) by more careful data sam-

Abstract

Translating to and from low-resource polysynthetic languages present numerous challenges for NMT. We present the results of our systems for the English–Inuktitut language pair for the WMT 2020 translation tasks. We investigated the importance of correct morphological segmentation, whether or not adding data from a related language (Greenlandic) helps, and whether using contextual word embeddings improves translation. While each method showed some promise, the results are mixed.

1 Introduction

This paper presents the neural machine translation (NMT) systems submitted by the University of Groningen to the WMT 2020 translation task[1] between Inuktitut and English in both directions (EN↔IU), describing both constrained and unconstrained systems where we investigated the following research questions:

- RQ1. Does morphological segmentation benefit translation with polysynthetic languages? Existing NMT research showed that morphological segmentation outperforms byte-pair encoding (BPE) (Sennrich et al., 2016) for some agglutinative languages. For example, rule-based morphological segmentation improved English-to-Finnish translation (Sánchez-Cartagena and Toral, 2016). and unsupervised morphological segmentation improved Turkish-to-English translation (Ataman et al., 2017). We investigate if morphological segmentation also improves translation performance for polysynthetic languages, and if effects differ depending on translation direction.
- RQ2. Does the use of additional data from a related language, Greenlandic (KL), improve the outcome? Due to the scarcity of EN–IU parallel data, we investigate if adding Greenlandic data to the Inuktitut data to train a multilingual NMT system (Johnson et al., 2017), improves the performance of the NMT systems on the unconstrained task (Zoph et al., 2016).
- RQ3. Does the translation benefit from using contextual word embeddings? The use of such embeddings has proven beneficial for many tasks in natural language processing (Devlin et al., 2019), including MT (Zhu et al., 2020), so we deem it sensible to test this for a polysynthetic language, which we will do by means of masked language modelling pre-training.

In section 2 we present the main data and evaluation measures used. In section 3 we present experiments with morphological segmentation methods. Section 4 presents the results of our translation systems, and in section 5 we present our conclusions.

2 Corpora and Evaluation

The preprocessing followed the procedure of Joanis et al. (2020), carrying out the following steps in order: spelling normalisation and romanisation (only for IU), punctuation normalisation, tokenisation, and truecasing (only for EN). Parallel data is additionally filtered (ratio 15, minimum and maximum length 1 and 200, respectively). As monolingual data we use the Common Crawl (CC) corpus for Inuktitut, and the 2019 version of Newscrawl for English. For CC we also filter out duplicate lines, lines of which more than 10% of the characters are neither alphanumerical nor standard punctuation, and lines that contain more than 200 words. These

[1] http://www.statmt.org/wmt20/translation-task.html

Proceedings of the 5th Conference on Machine Translation (WMT), pages 274–281
Online, November 19–20, 2020.

steps reduce the amount of data considerably, from 164,766 to 28,391 lines. Line deduplication is also applied to Hansards.[2]

Since the parallel training data contains only Hansards, we used part of the news from the dev set as additional training data by splitting the news part of the dev set: the first 1859 lines are used for training and the last 567 for development. We refer to these subsets as `newsdevtrain` and `newsdevdev`, respectively.

Tables 1 and 2 show the parallel and monolingual datasets, respectively, used for training after preprocessing.

		Words	
Corpus	**Sentences**	**EN**	**IU**
Hansards	769810	17303903	8236210
Newsdevtrain	1859	40154	24121

Table 1: Preprocessed EN–IU parallel training data.

Lang.	**Corpus**	**Sentences**	**Words**
IU	Common Crawl	28391	381805
EN	Newscrawl	5000000	143776337

Table 2: Preprocessed monolingual training data.

During development, we evaluated our systems on the news and Hansards portions of the development set, separately. We used two automatic evaluation metrics: BLEU (Papineni et al., 2002) and CHRF (Popović, 2015). CHRF is our primary evaluation metric for EN→IU, due to the fact that this metric has been shown to correlate better than BLEU with human evaluation when the target language is agglutinative (Bojar et al., 2016). BLEU is our primary evaluation metric for IU→EN systems, as the correlations with human evaluation of BLEU and CHRF are roughly on par for EN as the target language. Prior to evaluation the MT output is detruecased (only EN) and detokenized with Moses' scripts.

3 Segmentation with intrinsic evaluation

Like many polysynthetic languages, Inuktitut has a high degree of inflection and agglutination, leading to very long words with a very high morpheme-to-word ratio (Mager et al., 2018). By our estimation, Inuktitut has an average of around 4.39 morphemes per word.

This means on average there are more potential boundaries, as well as more actual segmentation boundaries to locate per word, making segmentation particularly challenging.

Inconsistent segmentation harms an NMT model's ability to extract knowledge, because it reduces the frequency and activation of all vocabulary items during training, such that for each individual element in the vocabulary is found in fewer contexts. At inference, inconsistent segmentation can result in morphs that are out-of-vocabulary, resulting in information loss.

We hypothesize that linguistically correct segmentation may be particularly beneficial for translation with polysynthetic languages because it could provide more consistent isolation of concepts into subwords.

We evaluated a broad pool of segmenters to determine how close various methods can achieve linguistically correct segmentation, comparing results to reference segmentations obtained from the Inuktitut Computing GitHub repository[3]. This repository contains 1096 Inuktitut words, manually segmented at the National Research Council of Canada (NRC).

Our experiments include: Rule-based with Uqailaut[4]; Morfessor Baseline (semi-supervised) (Creutz and Lagus, 2002); Morfessor FlatCat (semi-supervised) (Grönroos et al., 2014); LMVR (unsupervised) (Ataman et al., 2017); and Neural Transformer segmentation (supervised).

We used Uqailaut's rule-based segmenter to create additional annotated segmentations used to train the supervised and semi-supervised systems. In total 600,000 segmentations of unique words from the Hansard training dataset were created. All semi-supervised and unsupervised systems were trained with the Hansard training corpus. For training semi-supervised methods, we use 60,000 of the collected segmentations with Uqailaut as annotated training data, and another 3,000 as validation data. For LMVR we set the maximum lexicon size to 20,000.

Related to our work, a previous study (Kann et al., 2018) compared segmentation methods based on their ability to generate linguistically correct segmentations for several low-resource Mexican polysynthetic languages. Their proposed RNN-

[2]We used Hansards for training with and without deduplication and the former led to better results.

[3]https://github.com/LowResourceLanguages/InuktitutComputing

[4]http://www.inuktitutcomputing.ca/Uqailaut/info.php

based neural approach outperformed baselines of other common approaches, so we also tested a neural segmentation method, but instead of an RNN we use a Transformer architecture. We implement this neural segmenter using Marian[5]. On the source side, the unsegmented words are used as input data. The corresponding segmented words are used as target data. On the target side we denote the segmentation boundary by adding a boundary token (@), like in the following example:

Source: a k i r a q t u q t u t

Target: a k i r a q @ t u q @ t u t

We trained three neural segmentation models: one on all 600,000 annotated segmentations, plus two with 45,000 annotated segmentations, one with only unambiguous annotations[6] and one with a random selection from the pool of 600,000.

Table 3 shows the intrinsic evaluation results. Similar to Kann et al. (2018), the neural segmentation model improves over existing segmentation methods by a considerable margin. The neural model trained on the 45,000 unambiguous data outperformed the model trained on all the 600,000 segmentations, suggesting that the consistency of the data is more important than the quantity. The other segmenters clearly struggled with the long words, often splitting words into a combination of very long root, and very short morphs. FlatCat scored the highest of the existing methods on both F1 and accuracy.

Unfortunately, both the neural and rule-based models sometimes fail to segment the input word. This makes them unfit to use in a translation system; since some words are left unsegmented, and this leads to a very large vocabulary size which hurts the translation performance. Micher (2017) previously explored improving the coverage of the Uqailaut morphological analyser with the use of an RNN based approach. In Micher (2018), an SRNN extension to the Uqailaut morphological analyzer is used in an SMT system, and yields a statistically significant improvement for IU→EN translation compared to the unextended rule-based analysis. Similar to their approach, we combined the best performing models of the intrinsic evaluation, to construct a custom 3-step segmenter to improve the coverage. This method initially applies the rule-based segmenter. If the rule-based segmenter fails, it falls back on the Transformer (unambiguous 45K) model. For non-alphabetic tokens we apply the BPE 5K model, because the Transformer fails for these tokens.

[5]https://marian-nmt.github.io/

[6]Out of the 600,000 words, Uqailaut produces unambiguous segmentations for 45,000 words

Method	F1	Acc.	Fail (%)
M. Baseline	0.317	0.222	-
M. FlatCat	0.397	0.328	-
LMVR	0.296	0.240	-
Trf. (45K rand.)	0.378	0.297	-
Trf. (45K single)	**0.680**	**0.539**	0.09
Trf. (all 600K)	0.625	0.433	0.55
3-Step	0.741	0.696	-
3-Step + LMVR	0.292	0.258	-
Rule-based	0.716	0.681	11.50

Table 3: Results of the intrinsic evaluation for each segmentation approach. The F1 score is calculated on segmentation boundaries, while the accuracy is calculated on the full segmentation. The *fail* statistic signifies the percentage of words that the approach failed to reconstruct for the methods for which that can occur.

Preliminary experiments with this approach still resulted in a very large vocabulary size. To reduce the vocabulary size further and combine all steps into a single model, afterwards we perform vocabulary reduction using LMVR. We specify a lexicon size of 20,000, which results in an actual vocabulary size of 41,024. The vocabulary reduction applied to the 3-step model leads to a drop in F1 and accuracy. This could be either because the vocabulary reduction leads to fewer segmentation boundaries per word, or because LMVR changes the model too much.

4 Translation experiments

Unless mentioned otherwise, the translation models are trained using Marian (Junczys-Dowmunt et al., 2018) v1.9.0 on an Nvidia V100. The translation models use the `transformer` model type with default settings. We use the `ce-mean-words` cost function. We perform a validation run every 5,000 update steps and apply early stopping after the validation cost stalls 5 times in a row. The model with the best translation score on the validation set (Section 2) is stored for each experiment.

4.1 Constrained Systems

Our constrained systems can be divided into four groups according to the techniques used: tags, backtranslation and domain-specific data (section 4.1.1), morphological segmentation (4.1.2),

contextual word embeddings (4.1.3) and ensembling and fine tuning (4.1.4).

4.1.1 Initial Systems

In these systems, following Joanis et al. (2020), we segment the training data with BPE (Sennrich et al., 2016) separately on each language. 5,000 and 2,000 merges are performed on both languages for MT systems into EN and IU, respectively.

Table 4 shows our initial constrained systems and their results on the development set.

	IU→EN		EN→IU	
System	**News**	**Hansards**	**News**	**Hansards**
1	14.73	29.62	40.29	52.97
2	17.96	29.7	47.47	**54.20**
3	17.24	28.88	**51.31**	53.86
4	**22.24**	**30.05**	NA	NA

Table 4: Results of the initial constrained systems for both translation directions and both dev sets. The scores are BLEU (IU→EN) and CHRF (EN→IU). Best result shown in bold.

Initial Systems System 1 is trained on Hansards. System 2 adds `newsdevtrain`, oversampled (5 times) given its small size compared to the other corpus used for training, i.e. Hansards (see Table 1). This results in a notable improvement for news (over 3 points into EN and over 7 into IU) and, as expected, a minor difference for Hansards.

Tags System 3 differs from system 2 in that each source sentence is preprended with a tag (<H> for Hansards and <N> for news); this degrades results into EN, but improves results into IU considerably for news (almost 4 points), with minimal change to Hansards.

Backtranslation In system 4 different amounts of newscrawl 2019 were backtranslated and concatenated to the training data of previous systems 3 and 2, with (<B>) and without a tag, respectively. This system is used only for IU→EN and its best results were obtained with 1 million sentences without tags; compared to system 2, adding backtranslation results in over 3 points improvement for news (22.2 vs 18) and a smaller increase for Hansards (30 vs 29.7).

We also explored the use of backtranslation for EN→IU. CC (backtranslated into EN) was concatenated to the training data of the previous systems 3 and 2, with and without a tag, respectively. Results were very similar. We conjecture this was due to its limited size and noisy nature, since it is web crawled.

	IU→EN		EN→IU	
Model	**News**	**Hans.**	**News**	**Hans.**
BPE 5K	14.77	**28.31**	32.52	39.81
Morfessor	13.39	26.82	28.75	38.20
FlatCat	12.86	26.49	23.25	29.88
LMVR	14.98	27.50	**34.84**	**41.25**
Trf. (single)	11.31	24.56	31.34	39.33
3-St.+LMVR	**15.25**	28.06	34.51	40.54

Table 5: Results of the extrinsic evaluation for the selected segmentation methods. Scores for IU→EN are in BLEU, and for EN→IU are in CHRF. Best results for each dataset and metric are in bold. All models are trained only on the Hansard training data.

Topic-specific News Because the texts in both dev sets concern (mostly) events in Nunavut, we hypothesised that Nunavut-related news *only* from our backtranslated news might be beneficial. We selected only documents from the document-delimited version of `newscrawl` that contain any word from a topic list.[7] Topic words were picked due to being frequent in `newsdevtrain` and unambiguously related to Nunavut. 2,845 newsstories were extracted, after preprocessing 150,472 sentences and 3,220,925 words. We trained systems with this topic-specific backtranslated news as well as a similar amount of news randomly selected. Contrary to our hypothesis, the random news outperformed topic-specific news: 18.92 vs 20.2 BLEU on the news part of the dev set.

4.1.2 Morphological segmentation

We train translation models for the segmentation methods described in Section 3. For these experiments, the English data was segmented using BPE with 5,000 merges. Results are reported in Table 5. Both models that use LMVR for vocabulary reduction perform well for translation into IU, outperforming BPE on both Hansard and News data. There seems to be no benefit from the use of a more morphologically correct segmenter, as the highest scoring segmenters on the intrinsic evaluation (Table 3) generally performed worse on the extrinsic evaluation.

Based on the results of this extrinsic evaluation, we decide to use the BPE, LMVR, and 3-Step seg-

[7] Baffinland, Inuit, Inuits, inuits, Inuktut, Inuktitut, Iqaluit, Kivalliq, Nunatsiaq, Nunavik, Nunavut and Savikataaq.

mentations in our best systems so far (system 3 into IU and 4 into EN, see Table 4). Different amounts of BPE merges were tried for EN. The best results were obtained with 32,000 into IU and 20,000 into EN, whose results are reported in Table 6. The LMVR segmenter improved the translation into IU for the Hansard data, but not for news. For translation into EN there was no improvement from using a different segmenter.

	IU→EN		EN→IU	
System	**News**	**Hans.**	**News**	**Hans.**
Sys. 4 & 3 resp.	**22.24**	**30.05**	**51.31**	53.86
LMVR	21.89	29.20	50.36	**54.45**
3-Step + LMVR	21.79	29.66	50.19	52.18

Table 6: Results of the constrained systems that use morphological segmentation for both translation directions and both dev sets. The scores are BLEU (IU→EN) and CHRF (EN→IU). Best results shown in bold. The IU→EN models are based on system 4, while the EN→IU models are based on system 3 (Section 4.1.1).

4.1.3 Contextual Word Embeddings

With the recent success of pretrained contextual embeddings in MT (Lample and Conneau, 2019; Zhu et al., 2020), we try using this technique for a polysynthetic language. Specifically, we use the XLM model (Lample and Conneau, 2019), not only as a means of having contextual embeddings, but also to leverage available monolingual data for the task. For our XLM experiments, pretraining uses both masked language modeling (MLM) and translation language modeling (TLM). For the NMT training step, we include both denoising and back-translation for the monolingual data, as well as the standard MT training with the parallel data. Both the pretraining step and the NMT step use the monolingual data and the parallel data.

Pretraining	**IU→EN**	**EN→IU**
No	**19.32**	48.36
Yes	18.58	**49.10**

Table 7: Comparison of pretrained and non-pretrained XLM systems on the News dev set. The scores are BLEU (IU→EN) and CHRF (EN→IU).

To observe the effect of language model pretraining, we train a model using the same data used in system 4 (see Table 4), with 10,000 BPE joins applied jointly to both languages.[8] See results in Table 7. Interestingly, the performance decreases for IU→EN but increases for EN→IU when pretraining is added. A possible explanation for this is that Inuktitut stands to benefit more from pretraining as it uses more of the total joint vocabulary (around 90% of the tokens compared to 70%).

To use the existing monolingual data (Section 2), we train XLM models with the News Crawl data for English and Common Crawl data for Inuktitut, as specified in Table 2. We also use Hansards and `Newsdevtrain` oversampled 5 times for parallel data. We try both tagging the data (with the Common Crawl data receiving its own tag, <C>) and leaving it untagged. We report the results in Table 8. The results indicate an improvement with tagged data in the EN→IU direction. This is consistent with our observations with Marian-run models (systems 2 and 3 in Table 4). The XLM model results show that despite removing back-translated parallel data, results are similar. This is almost certainly due to the on-the-fly back-translation present in the training scheme. The results for EN→IU are improved, which is likely due to even a small amount of Inuktitut Common Crawl data being indeed useful for training.

Tagged	**IU→EN**	**EN→IU**
No	**18.96**	48.9
Yes	16.76	**49.97**

Table 8: Results of the XLM models using monolingual data on the News dev set. Scores are BLEU (IU→EN) and CHRF (EN→IU).

The best result with XLM (19.32 BLEU for IU→EN) is almost 3 points behind the result of the system trained with Marian on the same data (22.24, system 5 in Table 4). A difference between these two systems is that XLM uses joint BPE (since the encoder is shared by both languages), while with Marian we used separate BPE models for each language, following Joanis et al. (2020). To have a fairer comparison, we train the same Marian model with joint BPE, which leads to a score of 21.43, still 2 points ahead of the XLM model.

This difference in performance can be attributed, we hypothesise, to two reasons: (i) the XLM models use a joint encoder and decoder for both languages so the model must learn to translate in both

[8] We apply BPE jointly as it follows the methods of Lample and Conneau (2019).

directions and (ii) differences in implementation of the Transformer model in both toolkits.

4.1.4 Ensembles

For our final submissions, we depart from the best system so far (3 into IU and 4 into EN) and experiment with the use of ensembling and fine-tuning techniques. While some systems that used morphological segmentation performed similarly to those with BPE, their ensembles lagged behind. We therefore focused on BPE-based systems. In the following experiments we varied the value of the decoder's penalty length based on results on the dev set (until now we had used the value 1.0): for IU→EN we use 0.8 for news and 1.4 for Hansards while for EN→IU 1.2 was used for both dev sets. The results are shown in Table 9.

	IU→EN		EN→IU	
System	**News**	**Hans.**	**News**	**Hans.**
best single system	22.38	38.41	51.83	54.35
ens normal	23.72	39.07	52.92	55.05
ens FT	24.01	**39.72**	53.19	55.31
ens normal + FT	**24.25**	39.67	**53.46**	**55.39**

Table 9: Results of the constrained systems that use ensembling (referred to as ens) and fine tuning (FT) for both translation directions and both dev sets. The scores are BLEU (IU→EN) and CHRF (EN→IU). Best results shown in bold.

Ensembles are built by training the same system with different seeds (4 into EN and 3 into IU) and picking the model from each training seed with the highest score. These bring consistent improvements for both directions and dev sets: from 0.66 points for IU→EN Hansards to 1.34 for news in the same direction (row "ens normal" in Table 9).

We fine tune on `newsdevtrain` on its own and together with backtranslated news (only into EN) for the news dev set and on Hansards for the Hansards dev set. The ensembles of fine-tuned models bring consistent improvements compared to ensembles of non fine-tuned systems (row "ens FT" versus "ens normal" in Table 9). Finally, ensembling both fine-tuned and no fine-tuned systems (row "ens normal + FT" in Table 9) pushes the scores further (except for Hansards IU→EN) though rather slightly.

4.2 Unconstrained Systems

4.2.1 Data Acquisition

We use three additional parallel corpora that we acquired. First, we use data from the Inuktitut magazine[9], which contains parallel articles about Inuit culture and society in Inuktitut (IU), English (EN), and French; we manually extracted the text (IU syllabics, romanized IU, and EN) from several recent issues. Second, we use data from a Kalaallisut (KL) magazine[10] containing parallel news articles in Danish (DA) and KL. These texts were also manually extracted. Thirdly, parallel data from 21 multilingual websites containing DA and KL texts, was crawled using bitextor[11].

4.2.2 MT with Unconstrained Data

These datasets are pre-processed just like the ones from the constrained setup. In addition, we select a subset using their sentence alignment confidence score.[12] The KL crawl is paired with Danish. We performed language classification on the Danish data using LangID[13], removing any sentence pairs not classified as Danish. Danish was translated into English with a pretrained DA→EN system[14] from OPUS-MT (Tiedemann and Thottingal, 2020). Dataset details are presented in Table 10.

		Words	
Corpus	**Sentences**	**EN**	**IU/KL**
IU Magazine	1134	29312	18152
KL Magazine	657	13009	7491
KL crawl	14778	277159	163468

Table 10: Preprocessed unconstrained parallel training data.

We added these corpora atop the best constrained systems (3 into IU and 4 into EN) one at a time and evaluated on the news part of the dev set. Table 11 shows the results. Into EN, adding IU magazine (for which we tried different oversampling values) did not improve results. Due to this and time limitations we did not add the remaining unconstrained

[10] *Atuagagdliutit*, https://timarit.is

[11] https://github.com/bitextor/bitextor

[12] The datasets were aligned with Hunalign, which provides a confidence score. We experimented with different thresholds and based on results on the dev set and used 0.4 for IU and KL magazines and 0.5 for KL crawl (Varga et al., 2007).

[13] https://github.com/saffsd/langid.py

[14] https://object.pouta.csc.fi/OPUS-MT-models/da-en/opus-2019-12-04.zip

data. Into IU, adding IU magazine (with a tag and oversampled 5 times) resulted in a slight improvement (51.9 vs 51.3). Adding to this KL magazine (also oversampled 5 times) degraded results, as did adding KL crawl (although to a lesser extent).

System	IU→EN	EN→IU
Best constrained (5, 3 resp.)	**22.24**	51.31
+ IU magazine	22.22	**51.88**
+ IU mag + KL mag		50.57
+ IU mag + KL crawl		51.27

Table 11: Results of the unconstrained systems for both translation directions and both dev sets. The scores are BLEU (IU→EN) and CHRF (EN→IU). Best results shown in bold.

5 Conclusions

This paper has reported on the systems submitted by the University of Groningen to the English↔Inuktitut translation directions of the news shared task at WMT 2020.[15] Our best results were obtained using well-established techniques, including oversampling domain-specific training data, backtranslation, tags, fine-tuning and ensembling.

The use of morphological segmentation (RQ1) led to results that were on par with those obtained by BPE in terms of automatic evaluation metrics. One problem is that existing morphological segmenters for low-resourced languages like Inuktitut suffer from poor coverage, which impedes making a complete comparison with more automatic methods. The extrinsic comparisons between segmenters showed that a more accurate morphological segmentation does not lead to improved translation performance. We further found that existing language agnostic segmenters struggle to produce correct segmentations on Inuktitut, and that neural methods appear to be more suitable for polysynthetic languages (cf. (Kann et al., 2018)) . Note also the importance of limiting the vocabulary size of morphological segmentation for MT, which could be explored further.

The use of additional data from Inuktitut did improve the results slightly, but not the addition of data from a related language, Greenlandic (RQ2). The fact that its usefulness was limited could be due to the fact that half of the test set was from a specific domain for which considerable amounts of data were already available to train (Hansards).

Finally, the use of contextual embeddings (RQ3), led to mixed results since it resulted in an improvement for one direction but a degradation for the other.

[15] We will provide links to the additional datasets we used in the camera-ready version.

Acknowledgments

We would like to thank the Center for Information Technology of the University of Groningen for their support and for providing access to the Peregrine high performance computing cluster. Thanks also to Ben Shaffrey, Barbera de Mol and Adna Bliek for help preparing the Inuktitut magazine data.

Abstract

In this paper we demonstrate our (OPPO's) machine translation systems for the WMT20 Shared Task on News Translation for all the 22 language pairs. We will give an overview of the common aspects across all the systems firstly, including two parts: the data preprocessing part will show how the data are preprocessed and filtered, and the system part will show our models architecture and the techniques we followed. Detailed information, such as training hyperparameters and the results generated by each technique will be depicted in the corresponding subsections. Our final submissions ranked top in 6 directions (English ↔ Czech, English ↔ Russian, French → German and Tamil → English), third in 2 directions (English → German, English → Japanese), and fourth in 2 directions (English → Pashto and and English → Tamil).

1 Introduction

This paper describes the OPPO's submission to the Fifth Conference on Machine Translation (WMT20) news translation shared task. We built Transformer (Vaswani et al., 2017)-based systems for all the directions, and applied several well-known, widely-used techniques, such as large-scale back-translation (Sennrich et al., 2016a) and forward-translation, model ensemble and reranking. Since all the systems share a roughly similar data preprocessing and training methods, to avoid duplication words, we will demonstrate the common knowledge in Section 2 firstly, which will be divided into two parts: the preprocessing part shows the data preprocessing pipeline and data filtering pipeline, the latter is generally composed by rule-based filtering and alignment-based filtering; the training part depicts the techniques we applied. Detailed information, including training hyperparameters, the results generated by each technique, and some other explorations will be listed in each corresponding direction in Section 3. Finally, we will summarize the report and indicate our final works. We used *marian* (Junczys-Dowmunt et al., 2018) to implement our systems for English ↔ {Khmer, Russian, Tamil} and French ↔ German task pairs, and *fairseq* (Ott et al., 2019) for the rest [1].

2 System Overview

We preprocess corpora in two stages. In the preprocessing stage, data is converted but not filtered. The common pipeline of preprocessing including the following steps:

- Remove non-utf8 characters
- Unescape html characters, e.g. "`>`" is converted to ">"
- Normalize different kinds of spaces and punctuations
- Tokenization
- True case

The last three steps are all processed by *moses* scripts. This pipeline is both applied for the parallel corpora and monolingual corpora, and true case models are generally trained on the mixture of parallel and monolingual datasets.

After preprocessing we filter the parallel corpora according to statistical information and alignment information, set the thresholds according to our previous experiences. For the statistic perspective, we mainly focus on some heuristic rules, contain but not limited in

[1] Choice on the training framework is only depends on personal habit.

Proceedings of the 5th Conference on Machine Translation (WMT), pages 282–292
Online, November 19–20, 2020.

- Pairs of which the source side and the target side are the same.
- Pairs contain blank lines.
- Pairs contain too long sentences (typically those have more than 200 words).
- Pairs that have abnormal source-target length ratios. The source-target length ratio is defined as the words count ratio between the source and the target. Typically the upper bound is 2.5 and the lower bound is 0.4.
- Pairs that have irregular character-word length ratios. The character-word length ratio is defined as the ratio between the count of characters and the count of words. Generally the upper bound is 12 and the lower bound is 1.5.
- Pairs that contain too long words. The length threshold for deciding whether the word is too long is 25 characters.

For the alignment perspective, we use *fast_align* (Dyer et al., 2013) to acquire the alignment scores from source to target and vice versa, then we average the scores for each pair to calculate a data pair's sentence-level alignment score. If a sentence pair's sentence-level alignment score is lower than -15, it will be expelled from the final dataset.

Having purified the corpus, we generally try to boost our systems using the following techniques, step by step:

1. Back-translation and forward-translation. Using the trained models to translate big volume, monolingual corpus from the target side to source side (i.e. back-translation (Sennrich et al., 2016a)) has been proved a very successful method in the past practices. In our experiments we can also see a general improvement brought by this technique, but it is not always the case. We also tried sampling based back-translation proposed in (Edunov et al., 2018), and this is effective only in certain cases as well. Furthermore, we found translating from the monolingal corpus from source language can also bring gains for the models (consistent with the phenomenon depicted in (Burlot and Yvon, 2018)), but in this situation arg-max based beam search should always be applied. We also followed (Hoang et al., 2018) to iteratively back-translate and forward-translate the corpus for several times.
2. Fine-tune. Adding too many synthetic parallel data generated by machine translation models could potentially modify the latent data distribution, and in some tasks the provided monolingual dataset has a small difference from the required domain (news), so after having trained models from the mixture of the original parallel corpus and the synthetic dataset, we continue fine-tune our models on the original parallel datasets only. Besides, for some low-resource tasks (such as tasks on Pashto and Khmer), even the official training datasets have relatively lower qualities, therefore only using training dataset to fine-tune is still not enough. For these tasks, we took one more step to fine-tune the models on the official released validation set, and we can always see a further improvement.
3. Ensemble. We generally train and fine-tune several different models and compose them into an ensemble model for a better result.
4. Reranking. With the ensemble model in the hand, we usually generate k-best candidates and use different scorers to score them. Scorers can be divided into three groups: **forward scorers** are just another ensemble models composed by the forward translation models (models translate the source language to the target language). Suppose we have trained 6 base forward models, typically we compose all of them together to form a big ensemble model for generating final results (this model is also used as a scorer), and then additionally enumerate all the 5-combinations of them to get another $\binom{6}{5} = 5$ scorers. Sometimes we furthermore enumerate all the 4-combination to get $\binom{6}{4} = 15$ more scorers for better reranking. **backward scorers** are ensemble models that actually back-translation models (models translate the target language to the source language), and **language models** are ensemble language models of target language. For each group of the scorers, we may use the left-to-right (l2r) models or right-to-left (r2l) models. For the latter form, we reverse the words orders for both source sentences and target sentences and train the models. The scores

generated by those scorers are used as features by the reranking model. For reranking, we mostly applied K-Batched MIRA (Cherry and Foster, 2012) or noisy channel (Yee et al., 2019).

3 Experiments Details

In this section we demonstrate our experiments details for each direction. For brevity we will ignore the same preprocessing and techniques we introduced in the previous section, mainly focus on how the techniques boosted the systems, and some other unique observations we found during the experiments.

In the text we will sometimes use ISO-639-1 two-letter codes for each language for short. Mapping between the abbreviations and full names can be found in Table 1. For example, when talking about the English → Chinese task, we may write `EnZh` for short, capitalizing the first letter of the ISO-639-1 codes for both source languages and target languages. For the direction pairs that involve English, sometimes we use the non-English language to indicate the whole pair, e.g. "Russian tasks" is used to indict the English ↔ Russian bidirectional task. As this report is in the news task scope, we sometimes use "task" as a synonym of "direction", e.g. "`EnZh` task" means the direction that translates English to Chinese.

By default, for every sub-task we combine all the official provided parallel corpora into a big dataset then clean it, use the cleaned corpus to train our baseline models. We strictly followed the requirement of the contest to use official released datasets only, so the systems we built are all constrained systems. If not mentioned, all of our baseline models are trained on the parallel corpus only, and all the scores reported are calculated by sacreBLEU (Post, 2018) based on the results which has been removed BPE symbols, detruecased and detokenized. We always apply BPE subwords (Sennrich et al., 2016b) on the corpora, usually train Transformer-Big models and tie the input and output matrices of the decoder. For all the tasks, we used Adam optimizer (Kingma and Ba, 2014). All the main systems (i.e. submitted results) are generated by the model listed in the **last** row of the corresponding table in each task.

Language Name	ISO-639-1 Code
Chinese	`zh`
Czech	`cs`
English	`en`
French	`fr`
German	`de`
Inuktitut	`iu`
Japanese	`ja`
Khmer	`km`
Pashto	`ps`
Polish	`pl`
Russian	`ru`
Tamil	`ta`

Table 1: ISO-639-1 codes for languages appear in news task of WMT20

3.1 English ↔ Chinese

3.1.1 Data Preprocessing

Compared from the other languages in the shared task, especially the languages which use alphabetical writing systems, Chinese has three typical characteristics, leading to three extra preprocessing steps we introduce below:

1. Chinese has two different writing systems: simplified Chinese and traditional Chinese. Following the statistical information mined from the original parallel corpus, we converted all traditional Chinese characters to their simplified counterparts.

2. Some websites use GB2312 to encode texts, therefore could convert Latin letters, digit characters and some other punctuation marks into *full width* form. Besides of some particular punctuation marks (full stops, commas, question marks and exclamation marks), we converted all the other symbols to half width form.

3. Chinese does not have explicit words boundaries, all the characters in the same clause are connected together. We used *pkuseg* (Luo et al., 2019) to segment words from the text.

It should be noted that Japanese also has these three features, so the same process is also applied in the English ↔ Japanese systems.

For data filtering stage, besides the heuristic rules we demonstrated in the previous section, we also compare the count of numbers and punctuation marks between source side and target side. If

the difference on number counts is greater than 3 or the difference on punctuation marks counts is greater than 5, the sentence pairs will also be removed.

3.1.2 Training

We combined the Chinese corpus and English corpus together to train BPE. The total BPE operation merge counts is 36K. After learning BPE operations, we built vocabularies for each language separately. The final vocabulary size for Chinese is 42K and for English is 23K. The model architecture for both directions are all Transformer-big. For `ZhEn` task, we tried different hyperparameters to train several models for getting ensemble model: learning rates ranged from 0.0003 to 0.0008, warmup steps fixed at 16,000, dropout ranged from 0.2 to 0.3. For `EnZh` task, the hyperparameters are all fixed (but tried different random seeds): learning rate was 0.0003, warmup steps was 15,000, feed forward network dimension was 15,000.

Entity substitution is experimented in the `ZhEn` system. We use *StanfordNLP* (Qi et al., 2018) to do the NER from parallel corpus and Chinese monolingual datasets (Because in Chinese monolingual datasets an annotation usually follows a foreign name). After having extracted all the entities, we didn't use alignment information to build the mapping between Chinese entities and English entities, but constructed such relationship just according to co-occurrence frequency information: suppose an entity "北京" occurs 50 times totally in the Chinese corpus from 20 sentences, and in the corresponding 20 English sentences "Beijing" occurs 51 times, "Shanghai" occurs 10 times, then we believe "北京" can be translated to "Beijing" but not "Shanghai". With the entity mapping rules, we then replace the entities in the sentence pairs by different tags `<tag1>`, `<tag2>` ... and train models. In the inference time, model generates results with those tags, and we take another post-edit stage to recover the entities, using the mapping rules as lookup tables.

Table 2 shows our systems for `ZhEn` task, and 3 shows our systems for `EnZh` task. For `ZhEn`, we back-translated 20M NewsCrawl and 17M NewsDiscussion monolingual datasets from English to Chinese, and forward-translated 13M Chinese monolingual dataset to English (including XMU, LDC, etc.).

System	BLEU	Improvement
Baseline	28.8	-/-
+ Back-translation	29.8	+1.0/+1.0
+ Forward-translation	34.5	+5.7/+4.7
+ Entity substitution	35.2	+6.4/+0.7
+ Fine-tuned by `newstest2017`	36.7	+7.9/+1.5
+ Ensemble & reranking	38.3	+9.5/+1.6

Table 2: Overview of our WMT20 Chinese → English systems. In the "Improvement" column we report two improvement amounts, the first one is the improvement amount compared with the baseline model (absolute improvement), and the last one is got from comparing with the previous step (relative improvement). Scorers for reranking are composed by 3 forward left-to-right (l2r) models, 3 forward right-to-left (r2l) models, 3 backward r2l models and 2 l2r Transformer language models.

System	BLEU	Improvement
Baseline	38.6	-/-
+ Back-translation (A)	39.1	+0.5/+0.5
+ Fine-tuned by parallel corpus	40.6	+2.0/+1.5
+ Fine-tuned by `newstest2017`	41.3	+2.7/+0.7
+ Forward-translation (B)	41.9	+3.3/+2.8
+ Ensemble	42.7	+4.1/+0.8
+ Reranking	43.2	+4.6/+0.5

Table 3: Overview of our WMT20 English → Chinese systems. BLEU scores are character-level. Model trained by adding forward-translation data (system B) is directly compared with the one trained by adding back-translation data only (system A). The two phases fine-tune, which is effective for the system A, has no obvious impact on system B

3.2 English ↔ Czech

3.2.1 Data Preprocessing

The officially released English ↔ Czech dataset has a different format from the other sub-tasks. The dataset, which is called CzEng 2.0 (Kocmi et al., 2020), contains not only parallel sentence pairs, but also the data source and three scores: alignment score calculated by dual conditional cross-entropy filtering (Junczys-Dowmunt, 2018), and language scores to show of how confident the source is Czech and the target is English. This extra information can further help us to filter the corpus.

Having noticed that both `CsEn` and `EnCs` tasks would be evaluated on long, document-level news datasets, and the CzEng dataset contains some document information, we first analyzed the data sources given in the dataset, to determine which of them are near to the destination domain, and which are far away. The data sources were observed from four aspects: 1. Are the sentences more colloquial or more formal? 2. How well the data is aligned? 3. Can the sentences form a paragraph? 4. Is the corpus also in the news domain?

With the features of the given data sources, we first set a hard condition to check whether a given sentence pair could be kept, then set different probabilities to randomly drop some pairs from certain data sources. Constrained by the paper length we cannot list all of the rules for all the data sources here, but we can take some examples. For the data of which the source is *news*, we kept all of them; at the other extreme, for the *commoncrawl* data, we first removed all the data pairs of which the alignment scores are below than 0.25, or the probabilities of the source sentences belonging to Czech are less than 0.9, then we removed 40% of the remained data randomly.

As the original dataset contains some paragraph information, we concatenated all the sentences that were originally in the same paragraph with a delimiter "|||" (for the sentences that come from the data sources of *subtitles*, *subtitleE* and *subtitleM*, we didn't concatenate them). After the initial filtering, we kept 24.24 million data pairs (If we add in the czeng-test data, the total volume is 24.44 million pairs). The kept data were then processed and filtered by the pipeline presented in the previous section, and we finally got 14.4 million pairs. Detailed preprocessing information can be found in Table 4.

Step	# Sentence pairs kept	Retention rate
Initial filtering	24.44 M	-
Deduplication	17.3 M	70.75%
Heuristic filtering	14.42 M	83.41%
Bad characters filtering	14.40 M	99.84%

Table 4: Preprocessing of the CzEng dataset. Official provided dataset contains alignment information so we didn't calculate alignment scores again, directly reused official information in the initial filtering step. In the "bad characters filtering" step, we printed a character frequency list from the dataset and set a threshold, removed all data pairs that contain irregular characters whose frequencies are lower than the threshold.

System	Score
full-doc	25.7
short-doc	26.3
no-doc	27.0

Table 5: Document-level model training experiments on the `EnCs` task. Scores are reported on `newstest2019` dataset

3.2.2 Model Training

As the evaluation for the `En` ↔ `Cs` tasks would be document-level, we first experimented to see if training a model on a dataset which contains many very long sentences can generate better translations for whole documents. We prepared the datasets in three different ways: 1. Concatenating all sentences that belong to the same document (as indicated in the original data sources), noted as "full-doc"; 2. Concatenating three consecutive sentences together, and select the middle one as the final result from the generated translation, noted as "short-doc"; 3. No special preprocessing, one line contains one sentence, noted as "no-doc". The experiments results are shown in Table 5.

From the results we can find that no extra document related preprocessing is the best preprocessing, so we continued our improvement based on the dataset which does not contain document-level information. We first trained two models based on the full CzEng 2.0 dataset (including all the official translated data). Models are all trained using Transformer-Big architecture with norm clipping set to 0.1, dropout set to 0.3, gradient update frequency set to 8, maximum tokens in a batch set to 6000. Warmup steps and learning rate varied from different experiments, the most common combination is warmup steps set to 16,000 and learning rate set to 0.001. During decoding the beam size is 5 and length penalty is 2.5 for `CsEn`, 2 for

Direction	Dataset	# Data pairs	Score
CsEn	All official released data	122 Million	34.0
CsEn	All official released data + 31M full sampling back-translated data	153 Million	34.1
CsEn	30M data sampled from official released data + 31M full sampling back-translated data	61.2 Million	34.2
EnCs	All official released data	122 Million	28.6
EnCs	All official released data + 28M full sampling back-translated data	150 Million	29.0

Table 6: Models prepared for the final back-translation and forward-translation. Czech monolingual datasets are the combination of all officially provided Newscrawl datasets, English monolingual datasets are sampled from Newscrawl 2019.

EnCs. The score of the CsEn model on offline test set (newstest2018) is 34.0 and the EnCs model on validation set (newstest2019) is 28.6. We use these two models back-translated and forward-translated several data, mixed our synthetic dataset with the original official whole datasets together, and trained several models. Models which have the best performances are selected for the final back-translation and forward-translation, which are listed in Table 6.

We composed the models shown above as two ensemble models, one for each direction, and did another round of back-translation and forward-translation again. For the EnCs task, we prepared two different final datasets as below. Two datasets are all generated by randomness-based back-translation, the difference is the full sampling one sample output words in the full vocabulary, whilst the top-k one restricts the sampling pool in the words that are listed in the top-k highest probabilities for each step:

- **Top-k sampling based dataset**, consists of 24 million data pairs from the original parallel corpus, 54 million officially provided forward-translated corpus (translated from English monolingual corpus), 50 million top-10 sampling back-translated corpus, and 15 million forward-translated corpus generated by our own ensemble model.

- **Full sampling based dataset**, consists of 24 million data pairs from the original parallel corpus, 54 million officially provided forward-translated corpus (translated from English monolingual corpus), 15 million forward-translated corpus generated by our own ensemble model, 31 million "old" full sampling back-translated data used in Table 6, and 36.7 million "new" full sampling back-translated data generated by ensemble model.

System	BLEU	Improvement
Baseline (parallel data only)	27.0	-/-
+ Officially provided synthetic data	28.6	+1.6/+1.6
+ Full sampling based back-translated data	29.0	+2.0/+0.4
+ Ensemble	29.2	+2.2/+0.2
+ FDA fine-tune	29.7	+2.7/+0.5
+ Fine-tune by Newstest2018 & reranking	30.5	+3.5/+0.8

Table 7: Overview of our WMT20 English → Czech systems. Scorers for reranking are composed by 16 forward left-to-right (l2r) models, 3 forward right-to-left (r2l) models, 3 backward r2l models and 3 l2r Transformer language models. We re-learned BPE after adding in the officially provided synthetic data and fixed it for the following steps. The BPE is learned separately and the merge operations count is 36K.

> The 36.7 million "new" back-translated data are generated after an extra cleaning step: As we observed the results generated by full-sampling back-translation sometimes contain very bad sentences, we check how many steps the decoder scores below -10 when decoding for a given input. If 20% of the step scores for a given sentence are below -10, then we discard the sentence pair.

We found the models trained by top-k sampling based dataset are generally worse than those trained by full sampling based dataset, therefore selected one top-k sampling based model and three full sampling based model to form the final ensemble model for decoding the test data. For the CsEn task, The final dataset is composed by 24 million original parallel data pairs, 24 million ensemble knowledge distillation data pairs, 50 million top-k sampling back-translated pairs, 10 million argmax beam search back-translated pairs, and 17 million forward-translated pairs. We trained 4 models using different learning rate (varied from 0.0008 to 0.0015) on this dataset, and fine-tuned them using original parallel dataset (fine-tuning on EnCs models does not bring any gains). The fine-tuned models are used for the final ensemble model. We also applied FDA algorithm (Biçici and Yuret, 2011) on the parallel dataset, picked out 5 million sentence pairs that are similar to the test set and fine-tuned on this small dataset.

The overview of our EnCs system is listed in Table 7, and CsEn system is listed in Table 8

3.3 English ↔ German

For En ↔ De tasks, we generally followed the process depicted in Section 2, cleaned 46.8 million data pairs and kept 30.6 million. For data

System	BLEU	Improvement
Baseline	31.9	-/-
+ Officially provided synthetic data	34.0	+2.1/+2.1
+ Full sampling based back-translated data	34.1	+2.2/+0.1
+ Original parallel data fine-tune	34.8	+2.9/+0.7
+ Ensemble	35.3	+3.4/+0.5
+ FDA fine-tune	35.5	+3.6/+0.2
+ Reranking	35.9	+4.0/+0.4

Table 8: Overview of our WMT20 Czech → English systems. Scorers for reranking are composed by 16 forward left-to-right (l2r) models, 3 forward right-to-left (r2l) models, 3 backward r2l models, 3 l2r Transformer language models and 1 all lower-cased Transformer language model which does not apply BPE on the training dataset.

System	DeEn BLEU	EnDe BLEU
Baseline	40.7 (-/-)	42.6 (-/-)
+ KD	-	44.9 (+2.3/+2.3)
+ Fine-tune on parallel corpus	-	45.3 (+2.7/+0.4)
+ Ensemble	41.9 (+1.2/+1.2)	45.9 (+3.3/+0.6)
+ Reranking	42.2 (+1.5/+0.3)	46.5 (+3.9/+0.6)

Table 9: Overview of our WMT20 German ↔ English systems. Reranking follows noisy-channel reranking (Yee et al., 2019). BLEU scores are reported on `newstest2019`. We learned BPE jointly for both tasks, merge operation is 32K. Learning rate for training is 0.001 and warmup steps is 4000

preprocessing, we removed sentence pairs that contain too many punctuation marks, and too many `[^A-Za-z]` characters. In both directions we found neither back-translation nor forward-translation could yield any gains. In the `EnDe` we found ensemble knowledge distillation (Freitag et al., 2017) could improve the effect but in the `DeEn` task it did not help. The overview of our `En` ↔ `De` system is listed in Table 9.

3.4 English ↔ Inuktitut

We just adapted the official preprocessing script in the syllabic form to process the corpus. BPE was learned independently and the merge operations count is 16K. The overview of our `En` ↔ `Iu` system is listed in Table 10.

System	EnIu BLEU	IuEn BLEU
Baseline	23.7 (-/-)	40.0 (-/-)
+ Back-translation	23.8 (+0.1/+0.1)	40.5 (+0.5/+0.5)
+ Knowledge distillation	-	41.3 (+1.3/+0.8)
+ Ensemble	24.3 (+0.6/+0.5)	41.9 (+1.9/+0.6)
+ Reranking	-	43.7 (+3.7/+1.8)

Table 10: Overview of our WMT20 English ↔ Inuktitut systems. Scores are reported on the official validation set

System	JaEn BLEU	EnJa BLEU
Baseline	22.0 (-/-)	37.0 (-/-)
+ Back-translation	24.5 (+2.5/+2.5)	41.4 (+4.4/+4.4)
+ Knowledge distillation	25.1 (+3.1/+0.6)	41.4 (+4.4/+0.0)
+ Ensemble	25.7 (+3.7/+0.6)	42.1 (+5.1/+0.7)
+ Reranking	26.1 (4.1/+0.4)	42.5 (+5.5/+0.4)

Table 11: Overview of our WMT20 English ↔ Japanese systems. Reranking follows noisy-channel reranking (Yee et al., 2019). BLEU scores are reported on the offline official validation set, for `EnJa`, we report the character-level score. We trained BPE separately for both tasks, merge operations is 32K. Learning rate for training is 0.0003 and warmup steps is 15000. We tried two different feed forward network dimensions, 4096 and 15000, and found no big differences

3.5 English ↔ Japanese

Our `En` ↔ `Ja` systems generally follow our `En` ↔ `Zh` systems depicted before, the difference was the upper bound of sentence length limit was set to 180 words, and we also set the lower bound to 3. For Japanese word segmentation we used *mecab* [2]. We cleaned 17.64 million parallel pairs and 13.7 million left. For back-translation, we used 16 million Japanese monolingual data and 13 million English monolingual data. The overview of our `En` ↔ `Ja` system is listed in Table 11

We tried to fine-tune the models using original parallel dataset, but didn't see any gain. After the test dataset was released, we applied FDA algorithm and extracted 5000 sentences from the training dataset which are the most similar to the test data. These sentences are mixed with the original validation dataset together, then 500 sentences are split out as a new validation set, the rest were used to fine-tune the models. This step improved our `EnJa` system by 1.3 BLEU and for `JaEn` it is 0.4 BLEU. However, as validation dataset changed and the scores on the new validation dataset were extremely high, this step is not listed in the Table 11.

3.6 English ↔ Khmer

For the Khmer tasks (and some other tasks in the following), The data preprocessing stages are slightly different from the way we depicted in the second section, stricter in the filtering part, which would remove the sentence pair if...

1. It is a duplicated example
2. The source or target side is empty

[2] `https://taku910.github.io/mecab/`

3. It contains urls

4. It has words that contain more than 4 consecutive repeated characters

5. It has unpaired quotation marks or parentheses (not applicable for Khmer tasks, but applied in the other tasks shown later)

6. The punctuation marks between the source and the target cannot be matched (not applicable for Khmer tasks, but applied in the other tasks shown later)

7. The length ratio between the source and target is greater than 2.0 or less than 0.5 (for Khmer is between 0.33 and 3)

8. More than half of the tokens are not from the indicated language. We designed a regular expression (noted as regex for short) for each language according to its alphabet, if the word failed to pass the regex, we say it is not from the given language. For example, the regex for English is `[a-zA-Z'-]+`

The maximum sentence length we allowed is also set to 200 words.

Similar to Chinese and Japanese, Khmer does not mark the words boundaries neither, so we used *SEANLP* [3] to do the Khmer word segmentation. After the cleaning, the 4.46 million pairs of sentences had 351K lines left.

It should be noted that the writing system of Khmer, Khmer script, is an *abugida*, means vowels do not have independent symbols, but are stuck after/above/below/in front of the consonants they follow. Roughly, the minimal meaningful unit of Khmer is called Khmer Character Cluster (KCC for short) (Huor et al., 2004), which should be regarded as a whole but actually contains several characters. Original BPE method would break KCC, but this is not what we expect, so we made some modification to keep it (the segmentation tool we used also considered this language feature). We combined Khmer corpus and English to train BPE together, the BPE merge operations count is 8K.

To train the model, we tried different learning rate ranged from 0.0001 to 0.0004, and different warmup steps from 2,000 to 32,000. The overview of our Km ↔ En system is listed in Table 12. Baseline model is trained by Transformer-mini (4-heads Transformer composed by 4 layers, embedding dimension set to 256, feed forward network dimension set to 1024), learning rate ranged from 0.0008 to 0.001, warmup steps fixed at 40,000. For back-translation, we used all officially provided Khmer monolingual data, and 27 million sentences for English from NewsCrawl 2019 and NewsCommentary 2019.

[3] https://github.com/zhaoshiyu/SEANLP

System	KmEn BLEU	EnKm BLEU
Baseline	5.7 (-/-)	2.38 (-/-)
+ Back-translation	13.0 (+7.3/+7.3)	10.15 (+7.77/+7.77)
+ Ensemble	13.6 (+7.9/+0.6)	10.56 (+8.18/+0.41)

Table 12: Overview of our WMT20 Khmer ↔ English systems. We didn't try fine-tune and reranking for these two tasks. BLEU scores are reported on the official offline validation set, reported on the word-level (different from the online character-level evaluation). for EnKm, the score is calculated by *multi-bleu*.

System	EnPs BLEU	PsEn BLEU
Baseline	6.0 (-/-)	12.3 (-/-)
+ Back-translation	10.7 (+4.7/+4.7)	14.5 (+2.2/+2.2)
+ Knowledge distillation	10.7 (+4.7/+0.0)	14.8 (+2.5/+0.3)
+ Ensemble	11.0 (+5.0/+0.3)	15.4 (+3.1/+0.6)

Table 13: Overview of our WMT20 English ↔ Pashto systems. BLEU scores are reported on the offline official validation set

3.7 English ↔ Pashto

Our Pashto systems used the similar process we described in the Japanese tasks. We cleaned the 1 million original parallel dataset and kept 700K pairs. BPE was jointly learned and the merge operations count is 10000, but the source language does not share vocabulary with the target. When training the models, the learning rate was set to 9×10^{-4} and warmup steps was 6000. The overview of our En ↔ Ps system is listed in Table 13

As what we did in the Japanese tasks, we selected 10000 sentence pairs from the training dataset according to the test data using FDA, mixed them with official validation set and devtest set to fine-tune our models for 5 epoch, then reranked the generated candidates. This improved our EnPs system by 1.6 BLEU and for PsEn the gain is 3.5.

3.8 English ↔ Polish

For En ↔ Pl tasks, we generally followed the process depicted in En ↔ De tasks, cleaned 10.3 million data pairs and kept 5.265 million. The overview of our En ↔ Pl system is listed in Table

System	EnPl BLEU	PlEn BLEU
Baseline	24.9 (-/-)	30.0 (-/-)
+ Back-translation	28.2 (+3.3/+3.3)	33.0 (+3.0/+3.0)
+ Knowledge distillation	28.8 (+3.9/+0.6)	34.6 (+4.6/+1.6)
+ Ensemble	29.9 (+5.0/+1.1)	35.1 (+5.1/+0.5)
+ Reranking	30.0 (+5.1/+0.1)	35.5 (+5.5/+0.4)

Table 14: Overview of our WMT20 English ↔ Polish systems. Reranking follows noisy-channel reranking. BLEU scores are reported on official released validation dataset.

14. Training methods listed are generally the same as what we did for En ↔ De, the only difference is we separately trained BPE for the two languages (so obviously they no longer share the vocabulary), but BPE merge operations count is still set to 32K.

3.9 English ↔ Russian

The data preprocessing for En ↔ Ru tasks is the same as demonstrated in the En ↔ Km part, the only difference is for Russian, our BPE merge operations count is set to 36K. The official released parallel dataset (without official synthetic dataset) is reduced from 43.8 million pairs to 26.5 million after the cleaning. For Russian tasks, we trained the model with some extra rounds of back-translation and knowledge distillation, which are:

- In the first round back-translation, we only used all the official released data including the synthetic part. After training had converged, we continued training on the parallel dataset.
- In the second round back-translation, we added in the back-translated results generated by our models, and continued training again.
- In the knowledge distillation step, we added in the knowledge distillation results on the base of the dataset produced in the previous step. After training had converged, models are continue trained using the mixture of original parallel dataset and the knowledge distillation results.

Full results can be referred to Table 15.

3.10 English ↔ Tamil

Similar to Khmer, Tamil language also uses abugida. So with the same idea, we need to determine the minimal unit to be separated during BPE training. Here we see syllables as the minimal unit, use *open-tamil* [4] to separate syllables, and use our modified *subword-nmt* to learn BPE separations. Cleaning process is the same as we described in the Khmer tasks, we cleaned all the parallel corpora which contains 660K pairs, and had 450K pairs left. For back-translation, we used all available Tamil monolingual corpus (27 million lines totally) and 16 million English sentences sampled from NewsCrawl 2019 and NewsCommentary 2019. BPE is learned jointly, the merge operations count is 10K. The overview of our En ↔ Ta system is listed in Table 16. In the fine-tune stage, we randomly kept 200 sentences from the newsdev2020 as the validation set, and the rest 1,789 sentences are used to fine-tune the model.

System	EnRu BLEU	RuEn BLEU

Table 16: Overview of our WMT20 English ↔ Tamil systems. BLEU scores are reported on newsdev2020. Configurations can be referred to the Khmer tasks. Steps with extra ∗ marks are evaluated in the tiny 200 lines new validation set.

3.11 French ↔ German

Our Fr↔De systems generally followed the steps we described in the Russian tasks, with two differences. The first is that we have only one round back-translation, since for this task pair no official back-translation dataset was released; the second is we didn't continue training using parallel corpus after the model had converged. Following the process described in the Khmer tasks, we cleaned the 13.7 million data pairs and kept 11 million. For

back-translation, we took 27 million French sentences (combination of NewsCrawl 2017-2019 and News Commentary datasets) and 40 million German sentences (from NewsCrawl 2019 only). We jointly learned BPE for the two langauges, the BPE merge operations count is 32K. We shared the vocabulary among the two languages and tied all embedding layers and output layer in the model. The overview of our Fr ↔ De system is listed in Table 17.

4 Conclusion

This report described OPPO's submissions to the WMT20 news translation task. We use the similar data preprocess and filtering strategy for all the tasks, contains statistical information based rules and alignment information based rules. We trained Transformer-Big models for all the directions and applied some mature techniques, like back-translation, ensemble model, fine-tune and reranking, they generally all brought gains for the final results. Our final submissions ranked top in 6 directions (English ↔ Czech, English ↔ Russian, French → German and Tamil → English), third in 2 directions (English → German, English → Japanese), and fourth in 2 directions (English → Pashto and and English → Tamil).

Abstract

This paper presents our work in the WMT 2020 News Translation Shared Task. We participate in 3 language pairs including Zh/En, Km/En, and Ps/En and in both directions under the constrained condition. We use the standard Transformer-Big model as the baseline and obtain the best performance via two variants with larger parameter sizes. We perform detailed pre-processing and filtering on the provided large-scale bilingual and monolingual dataset. Several commonly used strategies are used to train our models such as Back Translation, Ensemble Knowledge Distillation, etc. We also conduct experiment with similar language augmentation, which lead to positive results, although not used in our submission. Our submission obtains competitive results in the final evaluation.

1 Introduction

This paper introduces our work for the WMT 2020 News Translation Shared Task. We participate in three language pairs including Chinese/English (Zh/En), Khmer/English (Km/En), Pashto/English (Ps/En) and in both directions. After observation, we consider that the officially provided dataset has the acceptable size and quality therefore only participate in the constrained evaluation. Our method is mainly based on previous works but with fine-grained data cleaning techniques and language pair specific optimizations.

For each language pair, we perform careful multi-step cleaning on the provided dataset and only keep a high-quality subset for training. At the same time, several strategies are tested in a pipeline including Back-Translation (Edunov et al., 2018), Ensemble Knowledge Distillation (Freitag et al., 2017; Li et al., 2019), Forward Translation (Wu et al., 2019), Fine-Tuning (Sun et al., 2019), and Ensemble and Re-ranking (Ng et al., 2019a).

Due to the page limitation, we mainly introduce our methods and experiments on the Zh-En and En-Zh language pairs. Most of these methods are also employed on the Km/En and Ps/En pairs. Special optimizations regarding different language will be introduced separately.

2 Data

In this section, we describe the size and source of the dataset as well as our cleaning and filtering techniques.

2.1 Data Source

2.1.1 Zh/En

We use both bilingual and monolingual text to train the model. Regarding bilingual text, we merge the data from CCMT (7M), Wiki Titles v1 (1M), News Commentary v15 (0.4M) and a subset of UN Parallel Corpus (9M). We also select 10 million of Zh and En monolingual text from Xin Hua, XMU and News crawl respectively for back translation.

2.1.2 Km/En

We use the Para Crawl v5.1 (4.17M), Khmer and Pashto parallel data (0.29M) as the bitext corpus, and select 10M monolingual text from Common Crawl and news crawl 2018 for Km and En, respectively.

2.1.3 Ps/En

Similar to Km/En, we also use the Para Crawl v5.1 (1M), Khmer and Pashto parallel data (0.03M) as bitext and select 6.5M monolingual text from Common Crawl and news crawl 2018.

2.2 Data Pre-processing

For the Zh/En corpus, we use following operations to pre-process the data:

Proceedings of the 5th Conference on Machine Translation (WMT), pages 293–299

Operation	Zh-En			Km-En			Ps-En		
	Zh-En (bi)	Zh (mono)	En (mono)	Km-En (bi)	Km (mono)	En (mono)	Ps-En (bi)	Ps (mono)	En (mono)
Original	21	21.4	18	4.46	12.59	10	1.05	6.6	4.71
+ Deduplication	20.9	21.3	17.9	4.30	12.57	9.99	1.05	5.99	4.70
+ Lang-id filtering	20.4	19.6	17.9	2.82	11.13	9.93	1.02	5.69	4.38
+ Length filtering	20.1	19	17.9	2.71	10.54	9.90	0.94	4.97	4.14
+ Fast-align filtering	19.5	-	-	0.8	-	-	0.54	-	-
+ Data-selection	16.5	10	10	-	-	-	-	-	-

Table 1: This table shows the remaining data size of performing specific data cleaning and selection operations, where the unit is million (M). The bilingual (bi) and monolingual (mono) texts are both listed in the table for all three language pairs.

- Regarding Chinese text, we tokenize the text with Jieba[1] tokenizer, and create the BPE (Sennrich et al., 2016) vocab with 30K merge operations.
- For English text, we use moses[2] tokenizer and generate a BPE vocab with 32K merge operations.
- Bitexts with length ratios (source/target) greater than 3 are removed.
- Texts longer than 120 sub-tokens are removed.
- Texts with undesired fastText-langid (Joulin et al., 2016b,a) are removed.

For the Km/En and Ps/En corpus, following operations are performed on the data:

- Full-width texts are converted to half-width texts.
- De-duplication is performed.
- Texts which the source or target is empty are empty.
- Sentences with undesired fastText-langid (Joulin et al., 2016b,a) are removed.
- SPM with regularization (Kudo and Richardson, 2018; Kudo, 2018) is used for both language pairs.
- Fast-align (Dyer et al., 2013) is used to further clean the corpus.
- Sentences with more than 100 sub-tokens are removed.

[1]https://github.com/fxsjy/jieba
[2]http://www.statmt.org/moses/

During experiment, we notice that Km and Ps data has relatively low qualities, which need to be further cleaned in a stricter manner. Therefore, we gradually increase the threshold of fast-align, and remove about 50% of un-aligned text to improve the training data quality. Detailed data size of each step is shown in Table 1.

2.3 Data Selection

Data selection filters out bilingual or monolingual out-of-domain text from a given corpora. We perform data selection on the Zh/En UN dataset, of which the domain is different from news. To do so, we train a classifier to select texts classified as news from the UN corpus. In terms of the classifier, when selecting En→Zh bi-text, we sample the target language (Zh) text from UN and non-UN dataset with an equal size (e.g. 50000), and label them with UN and news tags. Then, we train a Fasttext (Bojanowski et al., 2017) classifier on the sampled set, and score the leftover UN set with the classification probability $P(y = \text{news}|x)$ to retrieve the top-k bi-text pairs, where k is set to 9M in the experiment. Note that even if the score is lower than 0.5, we still keep the sample if its rank is within top-k. This method is also used for Zh→En selection. Note that the selected En→Zh and Zh→En set can be overlapped but not exactly the same.

From the experiment, we find that data selection is quite effective in improving the BLEU score on WMT 2019 test set compared to using entire UN set with a 1.1 increase on Zh→En and a 1.6 increase on En→Zh, respectively.

For the Km/En and Ps/En pairs, we do not employ the data selection strategy, but carefully evaluate the performance of different sources in the training set and finally select the Common Crawl (Km) and News Crawl (En) as the monolingual corpus. KenLM (Heafield, 2011) is also used to filter the data.

3 System Overview

This section describes the model and techniques of our work. We basically perform such strategies sequentially. Our experimental result will be presented on each part.

3.1 Model

Transformer (Vaswani et al., 2017) has been widely used for machine translation in recent years, which has achieved good performance even with the most primitive architecture without much modifications. Therefore, we choose to start from Transformer-Big and consider it as a baseline. Two variants of Transformer are also evaluated during the experiments, which are the model with wider FFN layers proposed in (Ng et al., 2019b), and the deeper encoder version proposed in (Sun et al., 2019). Here, we call two variants Transformer-Large and Transformer-Deep. Our models are implemented with THUMT (Zhang et al., 2017), and trained on a platform with 8 V100 GPUs.

3.2 Back Translation

Following (Edunov et al., 2018), we use back translation (BT) to improve the system performance. However, unlike (Edunov et al., 2018), we use beam search to decode the pseudo source text because in the experiment we find that results from beam search is better than sampling.

To acquire better monolingual text, we also use the method introduced in the data selection section to filter the in-domain subset for BT. For Zh→En and En→Zh direction, we use texts in target language from our bilingual corpus as the in-domain set, monolingual corpus as the out-of-domain set to train the classifier, and finally select approximately 10 million of samples for each direction. The back translated corpus are merged with the original corpus, which improves the performance by 0.6 for Zh→En and 1.3 for En→Zh. For the Km/En pair, we use exactly the same method as Zh/En, but with monolingual corpus from specific language, resulting in improvements of 5.33 and 2.55 in terms of BLEU for Km→En and En→Km on the devtest 20. For Ps/En, BT is performed on the selected data described in previous section, achieving improvements of 8.08 (Ps→En) and 2.89 (En→Ps) in terms of BLEU on each direction.

3.3 Ensemble Knowledge Distillation

Ensemble Knowledge Distillation (Freitag et al., 2017; Li et al., 2019) improves the performance of a student model by distilling knowledge from a group of trained teacher model into it. Comparing with some soft label distillation methods, the EKD for NMT is relatively straightforward, which can be implemented by training the student on the combination of the original training set and the translation from the ensembled teacher model on the training set. In our experiments we ensemble four models as the teacher model to translate the training set. Then, compute the BLEU for each sentence against the ground truth target. We keep 2/3 of the top scored translations for distillation and merge them into the original training set.

Generally speaking, EKD can be performed in an iteration manner. However, this could bring negative influence on the final ensemble. Therefore, we only do it once. EKD improves the BLEU by 1.5 points on the Zh→En direction, but only 0.2 points on the En→Zh direction.

We didn't perform the EKD on the Km/En and Ps/En pairs due to the limitation of the corpus size.

3.4 Forward Translation

As described in (Wu et al., 2019), similar to back translation, the monolingual corpus in source language can also be used to create the forward translation text with a trained MT model, and the created forward and backward translation corpus can both be merged with the original bilingual data. This strategy can enlarge the data size to a large extent. There are basically four steps to perform the forward translation. Take En→Zh as an example: 1) train M models with EKD in both direction; 2) create pseudo corpus with the ensemble of M models on the monolingual corpus in both direction (SRC→TGT', TGT→SRC'); 3) merge the created corpus with others (BT + FT + EKD + bilingual). 4) train a new model on the mixed corpus. This technique improves the performance by 1.0 in terms of BLEU on En→Zh direction and 0.4 BLEU on Zh→En direction. We also perform this strategy on Km/En and Ps/En, which achieves the improvements of 2.50 and 1.17 on En→Km and Km→En directions; 0.18 and 0.65 on En→Ps and Ps→En directions.

Note that the model trained with this technique can be ineffective for ensemble, which means such training strategy might decrease the model diver-

sity.

3.5 Fine-tuning

Previous works demonstrate that fine-tuning a model on in-domain data such as last year's test set could effectively improve the performance of this year (Sun et al., 2019). In the experiment, we fine-tune the model on the newstest18 for Zh→En with 3000 tokens per batch for one epoch, successfully achieving 3.6 of BLEU improvements on the newstest19. Furthermore, we keep the test corpus with orilang as Zh from newstest18 for fine-tuning, gaining an additional 1.0 BLEU increase. However, this method only obtains 0.2 BLEU increase on the En→Zh direction.

Km/En and Ps/En are newly introduced language pairs in the evaluation this year, thereby have no previous test sets. Since an additional devtest set is provided in addition to the dev set, we fine-tune models on the dev set and test on the devtest set. The experiment shows that fine-tuning could achieve 5.12 and 0.13 of improvements for En→Km and Km→En; 0.59 and 0.79 for En→Ps and Ps→En.

3.6 Ensemble

Six Transformer models are trained with different seeds, including 2 deep, 2 big and 2 large variants. The ensemble model improves the performance by 1.0 on Zh→En and 0.4 on En→Zh in terms of BLEU.

For Km/En and Ps/En pairs, we trained 4 and 6 Transformer-Deep models for Km/En and Ps/En. However, due to the size limitation, the improvements of ensemble is not significant for these two language pairs.

3.7 Ensemble MT Fine-tuning

We perform an additional experiment, named Ensemble MT Fine-tuning. First of all, we fine-tune 6 models on the 18 test set and produce the translation (mt) with the ensemble of them on the 19 test set. Then, we fine-tune the un-fine-tuned 6 models with the mt, which surprisingly improves about 0.6 BLEU on En→Zh. But we see no improvements on Zh→En. This experiment is also performed on Km/En and Ps/En language pairs, but only obtains limited improvements.

While submission, we fine-tune all 6 models on 18 test set and produce the mt with the ensemble model on the 20 test set. We then use the mt of 20 test set to fine-tune the original un-fine-tuned model to get the final one.

3.8 Re-ranking

We also tested the noisy channel re-ranking proposed in (Ng et al., 2019b). However, we do not see consistent improvements on the news2019 and devtest set, thus we give up using the strategy in the submission for all three language pairs.

3.9 Similar Language Augmentation

We also investigate whether performing data augmentation with corpora in similar languages can boost system performances on low resource tasks like En/Km and En/Ps. Inspired by (Kudugunta et al., 2019) who propose the concept of language similarity that can be measured by the SVCCA score on hidden representations of a language pair.

We select top-two similar languages for Km and Ps, by referring to the (Kudugunta et al., 2019). We then collect a set of bilingual text from these languages and mix them into the original training set. For Ps, we collect bilingual corpus of Persian (Fa) and Urdu (Ur) for augmentation, and create

Table 6: The experimental result of Ps→En

a mixed corpora (Ps:Fa:Ur=8:10:3) with a size of 2.6M, much larger than the original bitext corpus. For Km, we collect Polish (Pl) and Corsican (Ca) as the augmentation language (Km:Pl:Ca=2:2:1) and mix them with the total size of 2.1M.

The experimental result shows that the augmentation improves the BLEU score by 1-3 points on all directions compared to merely training on the original training set, demonstrating that incorporate data of similar languages for data augmentation is effective. However, this advantage disappears when comparing with the strategy of using the Forward and Backward Translation with original language pair, because BT and FT fill the gap of the difference in the data size, and thereby fills the gap of the performance.

System	En→Ps dev	devtest
baseline	4.15	4.3
+ Strict Fast-align	6.0	6.13 (+1.83)
+ Back-Translation	9.01	9.02 (+2.89)
+ Forward-Translation	9.3	9.2 (+0.18)
+ Fine-tuning	-	11.02 (+0.59)
+ Ensemble	-	11.44 (+0.42)
2020 Submission		12.1

Table 7: The experimental result of En→Ps

Although this strategy works fine on a corpus with limited size, it is not as feasible as BT. At the same time, we understand that applying external similar language corpora is not allowed in the constrained track, and finally give up this method. But we would like to conduct further researches on this direction.

4 Results

This section presents the experimental results for each direction of all three language pairs in Table 2,3,4,5,6and 7, where the contribution of strategies introduced in previous sections are listed in each row.

5 Analysis

Here are several findings worthy of sharing during our experiments:

- We test different combinations of model architectures for ensemble, and find that the heterogeneous combinations often perform better than homogeneous combinations when the performance of each model is similar. We suppose that heterogeneous architectures are good at learning different kinds of patterns, which is potentially effective for ensemble.

- While performing data selection, we also test language models as described in (Ng et al., 2019b), but found that fasttext performed better than LMs. We consider this finding is

relatively intuitive because the objective of training the classifier could naturally distinguish features of inter-class samples and cluster inner-class samples, which should be more efficient than using LMs.

- When we perform back-translation and forward-translation on Km/En pairs, we find that no matter in which direction, monolingual text from news domain performs consistently better than that from wiki domain, but the bilingual texts are actually from wiki. The reason for the performance improvements contributed by news corpus might be that the size of the filtered bilingual corpus is small, therefore requires to learn more semantic patterns from BT and FT. Such semantic patterns appear more often in news corpus and thus surpass the loss caused by domain shifting.

6 Conclusion

This paper presents the submissions by HW-TSC on the WMT 2020 News Translation Task. For each direction in three language pairs, we perform experiments with a series of pre-processing and training strategies. The effectiveness of each strategy is demonstrated. Our experiments on similar language augmentation shows that corpora with similar languages can be used for performance improvements in low resource scenarios. Our submission finally achieves competitive result in the evaluation.

Abstract

In this paper we introduce the systems IIE submitted for the WMT20 shared task on German↔French news translation. Our systems are based on the Transformer architecture with some effective improvements. Multiscale collaborative deep architecture, data selection, back translation, knowledge distillation, domain adaptation, model ensemble and re-ranking are employed and proven effective in our experiments. Our German→French system achieved 35.0 BLEU and ranked the second among all anonymous submissions, and our French→German system achieved 36.6 BLEU and ranked the fourth in all anonymous submissions.

1 Introduction

We participate in the WMT20 shared news translation task in one language pair and two language directions, German→French and French→German. Our methods are based on techniques and approaches used in submissions from past years (Deng et al., 2018; Ng et al., 2019; Sun et al., 2019; Li et al., 2019; Xia et al., 2019), including the use of subword models (Sennrich et al., 2016), iterative back-translation, knowledge distillation, model ensembling and several techniques we proposed recently (Wei et al., 2020b,a).

For our submissions of two language directions, we adopt the deep transformer architectures (48-layer) based on multiscale collaboration mechanism (Wei et al., 2020b) as our baseline, which outperformed the standard `Transformer-Big` as well as shallower models significantly in terms of translation quality. We also use an iterative back-translation approach (Zhang et al., 2018) with the controllable sampling to extend the back translation method by jointly training source-to-target and target-to-source NMT models. Moreover, the knowledge distillation (Freitag et al., 2017) is employed to leverage the source-side monolingual data. For our final models, we apply a domain-specific fine-tuning process and model ensembling, and decode using noisy channel model re-ranking.

The paper is structured as follows: Section 2 describes the techniques we used, then section 3 shows the experimental settings and results. Finally, we conclude our work in Section 4.

2 Our Techniques

2.1 Multiscale Collaborative Deep Models

The structure of NMT models has evolved quickly, such as RNN-based (Wu et al., 2016), CNN-based (Gehring et al., 2017) and attention-based (Vaswani et al., 2017) systems. Deep neural networks have revolutionized the state-of-the-art in various communities, from computer vision to natural language processing. We adopt the deep transformer model proposed by our work (Wei et al., 2020b). Instead of relying on the whole encoder stack to directly learn a desired representation, we let each encoder block learn a fine-grained representation and enhance it by encoding spatial dependencies using a bottom-up network. For coordination, we attend each block of the decoder to both the corresponding representation of the encoder and the contextual representation with spatial dependencies. This not only shortens the path of error propagation, but also helps to prevent the lower level information from being forgotten or diluted. In this section we describe the details (as illustrated in figure 1) of our deep architectures as below:

Block-Scale Collaboration. An intuitive extension of naive stacking of layers is to group few stacked layers into a *block*. We suppose that the encoder and decoder of our model have the same number of blocks (i.e., N). Each block of the encoder has M_n ($n \in \{1, 2, ..., N\}$) identical layers,

Proceedings of the 5th Conference on Machine Translation (WMT), pages 300–304
Online, November 19–20, 2020.

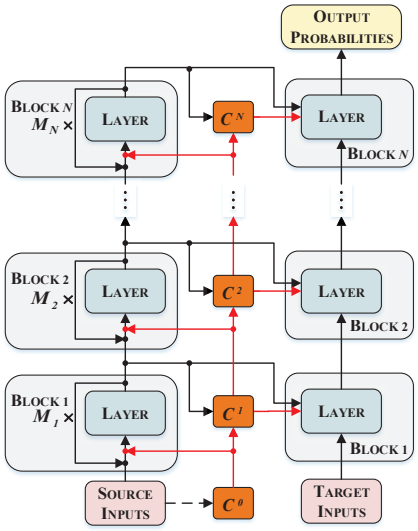

Figure 1: Illustration of Multiscale Collaborative Deep NMT Model. N is the number of encoder and decoder blocks. The n-th block of the encoder consists of M_n layers, while each decoder block only contains one layer.

while each decoder block contains one layer. Thus, we can adjust the value of each M_n flexibly to increase the depth of the encoder. Formally, for the n-th block of the encoder:

$$\mathrm{B}_e^n = \textsc{Block}_e(\mathrm{B}_e^{n-1}), \tag{1}$$

where $\textsc{Block}_e(\cdot)$ is the block function, in which the layer function $\mathcal{F}(\cdot)$ is iterated M_n times, i.e.

$$\begin{aligned} \mathrm{B}_e^n &= \mathrm{H}_e^{n,M_n}, \\ \mathrm{H}_e^{n,l} &= \mathcal{F}(\mathrm{H}_e^{n,l-1}; \mathbf{\Theta}_e^{n,l}) + \mathrm{H}_e^{n,l-1}, \\ \mathrm{H}_e^{n,0} &= \mathrm{B}_e^{n-1}, \end{aligned} \tag{2}$$

where $l \in \{1, 2, ..., M_n\}$, $\mathrm{H}_e^{n,l}$ and $\mathbf{\Theta}_e^{n,l}$ are the representation and parameters of the l-th layer in the n-th block, respectively. The decoder works in a similar way but the layer function $\mathcal{G}(\cdot)$ is iterated only once in each block,

$$\begin{aligned} \mathrm{B}_d^n &= \textsc{Block}_d(\mathrm{B}_d^{n-1}, \mathrm{B}_e^n) \\ &= \mathcal{G}(\mathrm{B}_d^{n-1}, \mathrm{B}_e^n; \mathbf{\Theta}_d^n) + \mathrm{B}_d^{n-1}. \end{aligned} \tag{3}$$

Each block of the decoder attends to the corresponding encoder block.

Contextual Collaboration. To model long-term spatial dependencies and reuse global representations, we define a GRU cell $\mathcal{Q}(\mathbf{c}, \bar{\mathbf{x}})$, which maps a hidden state $\mathbf{c}$ and an additional input $\bar{\mathbf{x}}$ into a new hidden state:

$$\begin{aligned} \mathrm{C}^n &= \mathcal{Q}(\mathrm{C}^{n-1}, \mathrm{B}_e^n), n \in [1, N] \\ \mathrm{C}^0 &= \mathcal{E}_e, \end{aligned} \tag{4}$$

where $\mathcal{E}_e$ is the embedding matrix of the source input $\mathbf{x}$. The new state C^n can be fused with each layer of the subsequent blocks in both the encoder and the decoder. Formally, B_e^n in Eq.(1) can be re-calculated in the following way:

$$\begin{aligned} \mathrm{B}_e^n &= \mathrm{H}_e^{n,M_n}, \\ \mathrm{H}_e^{n,l} &= \mathcal{F}(\mathrm{H}_e^{n,l-1}, \mathrm{C}^{n-1}; \mathbf{\Theta}_e^{n,l}) + \mathrm{H}_e^{n,l-1}, \\ \mathrm{H}_e^{n,0} &= \mathrm{B}_e^{n-1}. \end{aligned} \tag{5}$$

Similarly, for decoder, we have

$$\begin{aligned} \mathrm{B}_d^n &= \textsc{Block}_d(\mathrm{B}_d^{n-1}, \mathrm{B}_e^n) \\ &= \mathcal{G}(\mathrm{B}_d^{n-1}, \mathrm{B}_e^n, \mathrm{C}^n; \mathbf{\Theta}_d^n) + \mathrm{B}_d^{n-1}. \end{aligned} \tag{6}$$

2.2 Back-Translation with Controllable Sampling

Back-translation (BT) is an effective and commonly used data augmentation technique to incorporate monolingual data into a translation system. Back-translation first trains an intermediate target-to-source system that is used to translate monolingual target data into additional synthetic parallel data. This data is used in conjunction with human translated bitext data to train the desired source-to-target system.

In our work, we use an iterative back-translation approach to jointly train source-to-target and target-to-source NMT models. The process can be summarized as below:

- step 1: we train both a source-to-target model ($\mathcal{M}^0_{x\to y}$) and a target-to-source model ($\mathcal{M}^0_{y\to x}$) using the human translated data.
- step 2: we use $\mathcal{M}^t_{x\to y}$ to translate source-side monolingual data to target language, and use $\mathcal{M}^t_{y\to x}$ to translate target-side monolingual data to source language, where t starts from 0.
- step 3: we combine both the human translated data and pseudo data synthesized in step 2 to further optimize the two NMT models respectively.
- Repeat steps 2-3 until the models converge.

In practice, we repeat 3 times for steps 2-3. We apply the controllable sampling strategy (Wei et al., 2020a) to synthesize reasonable sentences which are at both high quality and diversity.

2.3 Knowledge Distillation and Ensemble

The early adoption of knowledge distillation (KD) (Kim and Rush, 2016) is for model compression. We use the same method as in Sun et al. (2019) that adopts hybrid heterogeneous teacher: base transformer, deep transformer, big transformer and RNMT+ (Chen et al., 2018). For each individual model, we use the other two models as the teacher model to further improve the performance. In addition, model ensemble is also used to boost the performance by combining the predictions of above four models at each decoding step.

2.4 Domain-specific Fine-tuning

Fine-tuning with domain-specific data is a common and effective method to improve translation quality for a downstream task. After completing training on the bitext and back-translated data, we train for an additional epoch on a smaller in-domain corpus. We first select 100K sentence-pairs from the bilingual as well as pseudo-generated data according to the filter method in Deng et al. (2018) and continue to train the model on the filtered data.

2.5 Reranking

N-best reranking is a method of improving translation quality by scoring and selecting a candidate hypothesis from a list of n-best hypotheses generated by a source-to-target model. For our submissions, we rerank the n-best hypotheses using two aspects as follows:

$$\log p(y|x) + \lambda_1 \log p(x|y) + \lambda_2 \log p(y) \quad (7)$$

The weights λ_1 and λ_2 are determined by tuning them with a random search on a validation set and selecting the weights that give the best performance.

3 System Overview

We submit constrained systems to both German to French and French to German translations, with the same techniques.

3.1 Dataset

We use all available bilingual datasets and select 10M bilingual data from WMT'20 corpora using the script `filter_interactive.py`[1]. We share a vocabulary for the two languages and apply BPE for word segmentation with 32K merge operations. For monolingual data, we use 18M German sentences and 18M French sentences from Newscrawl, and pre-process them in the same way as bilingual data. We split 9k sentences from the "dev08-14" as the validation set and use newstest 2019 as the test set.

+ KD & Ensemble	25.1	34.7
+ Fine-tuning	25.9	35.4
+ Reranking	26.5	36.3
WMT'20 submission		**36.6**

Table 2: SacreBLEU scores on French→German.

3.2 Model Configuration

We use the PyTorch implementation of Transformer[2]. We choose the `Transformer_base` setting, in which the encoder and decoder are of 48 and 6 layers, respectively. The dropout rate is fixed as 0.1. We set the batch size as 4096 and the parameter `--update-freq` as 16.

3.3 Results

Results and ablations for De→Fr Fr→De are shown in Table 1 and 2, respectively. We report case-sensitive SacreBLEU scores using SacreBLEU (Post, 2018)[3], using international tokenization for German↔French.

German→French For De→Fr, iterative BT improves our baseline performance on newstest 2019

[2]https://github.com/pytorch/fairseq

[3]SacreBLEU signatures: BLEU+case.mixed+lang.de-fr+numrefs.1+smooth.exp+test.wmt19+tok.13a+version.1.2.11, BLEU+case.mixed+lang.fr-de+numrefs.1+smooth.exp+test.wmt19+tok.13a+version.1.2.11

by about 2.5 BLEU. The addition of KD and model ensemble improves single model performance by 0.8 BLEU, but combining this with fine-tuning and reranking gives us a total of 2 BLEU. Our final submission for WMT20 achieves 35.0 BLEU points for German→French translation (ranked in the second place).

French→German For Fr→De, we see similar improvements with iterative BT by about 2.3 BLEU. KD, ensembling, and fine-tuning add an additional 1.4 BLEU, with reranking contributing 0.9 BLEU. Our final submission for WMT20 achieves 36.6 BLEU points for French→German translation (ranked in the fourth among anonymous submissions).

4 Conclusion

This paper describes CAS IIE's submission to the WMT20 German↔French news translation task. We investigate extremely deep models (with 48 layers) and exploit effective strategies to better utilize parallel data as well as monolingual data. Finally, our German→French system achieved 35.0 BLEU and ranked the second among all anonymous submissions, and our French→German system achieved 36.6 BLEU and ranked the fourth in all anonymous submissions.

Abstract

This paper describes our VolcTrans system on WMT20 shared news translation task. We participated in 14 translation directions. Our basic systems are based on Transformer (Vaswani et al., 2017), with several variants (wider or deeper Transformers, dynamic convolutions). The final system includes text pre-process, data selection, synthetic data generation, advanced model ensemble, and multilingual pre-training.

1 Introduction

We participated in the WMT2020 shared news translation task in 14 directions: English↔Chinese, English↔German, French↔German, English↔Polish, English↔Tamil,English↔Pashto,English↔Khmer, covering language pairs from high to low resources. In this year's translation task, we mainly focus on exploiting self-supervised and unsupervised methods for NMT to make full use of the monolingual data (Lin et al., 2020; Yang et al., 2019).

We aims at building a general training framework which can be well applied to different translation directions. Our models are mainly based on the Transformer (Vaswani et al., 2017). Techniques used in the submitted systems include iterative back-translation, knowledge distillation. We also employed several tricks to improve in-domain BLEU scores, typically in-domain transfer learning. We also experimented with a multilingual pre-training technique which we proposed recently (Lin et al., 2020).

2 Baseline Models

We apply two different NMT skeletons for the shared news translation as our baseline systems. We use the implementations in Fairseq(Ott et al., 2019). All models are trained with Adam optimizer (Kingma and Ba, 2014). We use the "inverse sqrt lr" scheduler with 4000 warm-up steps and set the max learning rate to 5e-4. The betas are (0.9, 0.98). During training, the batches are made of similar length sequences, so we avoid extreme cases where most sequences in the batch are short and we are required to add lots of pad tokens to each of them because one sequence of the same batch is very long. We limit the batch size to 8192 tokens per GPU, to avoid running out of GPU memory. Meanwhile, to achieve a larger batch size to improve the performance(Ott et al., 2018), we set the parameter "update frequency" to 8, and train the model on 8 GPUs, resulting in an actual batch token size = $8192 \times 8 \times 8$. During training, we employ label smoothing of 0.1 and set dropout rate (Hinton et al., 2012) to 0.2.

2.1 Transformer

Following Sun et al. (2019); Wang et al. (2018), we use different architectures for Transformer(Vaswani et al., 2017) to increase the model diversity and potentially get a better ensemble model.

- Transformer 15e6d: According to Sun et al. (2019), a transformer with larger encoder layer number can learn better representation of source sentence and get better BLEU scores. We increase the number of encoder layers from 6 to 15 layers in the transformer big architecture which is the same as the Deeper Transformer in Sun et al. (2019).

- Transformer Mid 25e6d and Transformer Mid 50e6d: To get much better BLEU scores, we further increase the encoder layer number from 6 to 25 (Transformer Mid 25e6d) and 50 (Transformer Mid 50e6d) for the transformer

Proceedings of the 5th Conference on Machine Translation (WMT), pages 305–312
Online, November 19–20, 2020.

big architecture. However, the model is too large and can not be trained with GPU, so we decrease the feed forward size from 4096 to 3072 and the embedding size from 1024 to 768.

- Transformer 15000ffn. According to Sun et al. (2019), the performance of the Transformer model is largely dependent on the dimensions of feed forward network. We use the same architecture as Bigger Transformer in Sun et al. (2019) which increases the feed forward size from 4096 to 15000, the attention dropout from 0.1 to 0.3 and the relu dropout from 0.1 to 0.3. The number of encoder and decoder layers remains 6.

- Transformer 128hdim and Transformer 256hdim. Bhojanapalli et al. (2020) shows that a transformer model with larger attention dimensions can also get better BLEU score. We increase the head dimension from 64 to 128 (Transformer 128hdim) and 256 (Transformer 256hdim). The number of encoder and decoder layers remains 6.

- DLCL 25layers. Li et al. (2019) proposes a transformer variant call DLCL and shows that this architecture can make deep transformer get higher BLEU.

2.2 Dynamic Convolution

We also apply dynamic convolution (Wu et al., 2019) architectures.

- Dynamic Convolution 7e6d: The dynamic convolution model with 7 encoder layers and 6 decoder layers which is the same architecture proposed in Wu et al. (2019).

- Dynamic Convolution 25e6d: We increase the encoder layer number from 6 to 25. For layers above 7, we set the kernel size to 31.

3 Experiment Techniques

3.1 Parallel Data Up-sampling

According to the experiments, data diversity matters for the whole system. Apart from splitting the monolingual data into several disjoint parts, we sampled the parallel data so that each model has different deviations on the parallel data. We tested bagging sampling (sample with replacement) and up-sampling(sample with replacement under the premise of using all data), experimental results show that when the amount of parallel data is inadequate with respect to the amount of model parameters (such as French↔German, English↔Polish, etc.), the bagging sampling method reduces the performance of the model; while when the amount of parallel data is abundant(such as English ↔ German), the bagging sampling method has no significant effects on the performance. On the contrary, the data up-sampling method never degrades the performance of the model.

mRASP: Multilingual Pre-training We employed a pre-training method mRASP, which pre-trains a universal multilingual neural machine translation model and fine-tune it on specific language directions. Basically, we pre-train a model using the provided parallel data on WMT2020 of English↔Khmer, English↔Inuktitut, French↔German, English↔Polish, English↔Pashto, English↔Tamil, on a shared vocabulary learned from the above parallel data plus provided monolingual data of all related languages. We learn a BPE sub-word vocabulary with 6000 merge operations. We up-sample the data from lower resource language data to balance data amount and only keep tokens that occur more than 10 times. Finally, we obtain a joint vocabulary of about 28000 tokens.

We fine-tuned the pre-trained model, for low-resource directions: Pashto→English, English↔Khmer and English↔Tamil. The baseline model initialized by this method performs better than the randomly initialized baseline model by a large margin. We pre-trained three mRASP models using the same training data: Transformer big, Transformer 15000ffn and Dynamic Convolution. We report in Table 1 the best score in each setting and direction, and find that mRASP significantly outperforms the baseline.

3.2 Tag Back-Translation

Recently, back-translation (Edunov et al., 2018) is a standard method to improve the translation quality by leveraging the large scale monolingual data. Starting from WMT19, the source of the test set is the natural text and the of the test set is the translationese text. We find the tag back-translation (Caswell et al., 2019) method can achieve better BLEU compared with previous methods proposed in Edunov et al. (2018).

Iter 1	27.5	32.6
Iter 2	27.8	32.7
Iter 3	28.2	33.3

Table 2: Iterative Joint Training for English↔Polish

To improve the data diversity among single models before model ensemble, we generated the back-translated data from different monolingual data using different baseline models, as illustrated in Figure 1. For high resource data (English, Polish, etc.), we divided monolingual data into several parts, each containing 10M sentences. However, for low resource data (Pashto), due to the lack of monolingual data, we use all monolingual data for all back-translation tasks.

3.3 Iterative Joint Training

Zhang et al. (2018) proposed an iterative joint training method for better usage of monolingual data from source side and target side. In each iteration, the S2T(source to target) model generates a S2T(target to source) synthetic data from the source side monolingual data and the T2S model generates a T2S synthetic data from the target side monolingual data. Then, the S2T and T2S model are trained with the new T2S and S2T synthetic data to improve the both models performance. In the next iteration, the S2T and T2S model can generate synthetic data with better quality and their performance can be improved further. We jointly trained the S2T and T2S model until they converge. Experiment results on English↔Polish shown in Table 2

3.4 Knowledge Distillation

Recently, knowledge distillation has been widely used to improve the performance of models (Sun et al., 2019; Li et al., 2019). In our knowledge distillation method, student model is trained to fit the output of teacher models. Concretely, we translate the source side monolingual data with an ensemble teacher and a right-to-left(R2L) (Liu et al., 2016) model teacher.

- Ensemble Model. We divided single models in the last joint training iteration into k groups (k=3 in our experiments, resulting in 3 models in each group) and ensemble models in one group to as the teacher model.

- R2L Model. We trained one R2L model for each ensemble group using the same data as anyone model in this group from the last iteration.

We then use pseudo parallel data from ensemble model as well as from R2L model to train the student model, without employing parallel data.

3.5 Advanced Tricks

Top-k Checkpoint Average Different from the conventional checkpoint average approach, which is to average continuous K checkpoints, we average K checkpoints which have the highest BLEU scores on the valid set, and find that this strategy usually leads to significant BLEU improvements over single checkpoints.

Random Ensemble We adopt a simple yet effective strategy in model ensemble. Rather than select the best checkpoint from each model (a.k.a. greedy search), we enlarge the search space: choose one checkpoint from top-k checkpoints from each model, and randomly select N combinations from the entire search space, see Figure 2.

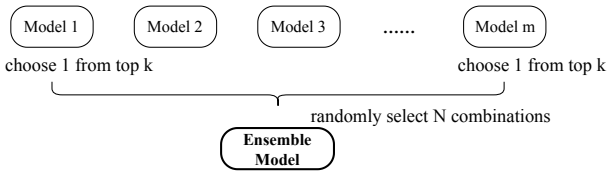

Figure 2: Illustration of Random Ensemble

In domain Fine-tuning There exists a domain mismatch between the obtained system trained with provided parallel or monolingual training data and the target test set. In order to alleviate this mismatch, and to improve the translation performance in the domain of the target test set, we fine-tune the best single models with development sets for 1-2 epochs.

4 Settings and Results

For all news tasks, all ParaCrawl corpus is cleaned by the script proposed by Xia et al. (2019). We trained the baseline using the sampling method described in Section 3.1 with different architectures showed in Section 2. For the low resource language pair (English↔Pashto), as showed in Section 3.1, we pretrained three multilingual models with different model architectures (DLCL 25layers, Transformer 15000ffn and Dynamic Convolution 25e6d) on all parallel data available in WMT20 except the English↔Chinese to avoid a large dictionary[1] and fine-tuned the pre-trained models on the their own parallel data with different data sampling strategies to get 9 baseline models[2]. Then we applied the tag back-translation, joint training, knowledge distillation and random ensemble methods as described in Section 3 to get the final translation system. All BLEU scores were reported with SacreBLEU(Post, 2018).

4.1 Chinese→English

Final Submission We submitted our VolcTrans online system (unconstrained). The final submission achieves 36.6 BLEU. You can get access to VolcTrans online system on `http://translate.volcengine.cn/`.

[1]Large dictionary leads to large parameter size in embedding

[2]We randomly combine sampling strategies and model architectures to get 9 baseline models for each direction. The performances of the 9 baselines is not the point, what we want is the model diversity among single models

4.2 English→Chinese

For English→Chinese, we train English↔Chinese jointly. We use all parallel data available: News Commentary v15, Wiki Titles v2, UN Parallel Corpus V1.0, CCMT Corpus and WikiMatrix. After data filtering, XM parallel data remained. We use MosesTokenizer for English and Jieba for Chinese. After the pre-processing, separate BPE vocabulary is learned with 32000 merge operations for both English and Chinese on the parallel data. We sample parallel data of ratio 100%, 110% and 120% with replacement from all parallel data. Then we train 3 baselines with Transformer Mid 25e6d, Transformer Mid 50e6d and Dynamic Convolution 25e6d architectures respectively, resulting in 9 baseline models. We employ Newscrawl data as monolingual data for English. The total amount of monolingual data is 90M, containing all Newscrawl 2019 data and others sampled from Newscrawl 2014 to 2018. For Chinese, we employ Newscrawl data, CCMT data and LDC data. We split the Chinese into 3 parts, each contains 8M sentences. For iterative back translation stage and ensemble knowledge distillation stage, each model is combined with different English monolingual data part. Since there are only 3 parts of Chinese monolingual data, we use each part for 3 times at each stage. At the ensemble knowledge distillation stage, we also employ disjoint monolingual data as the distilling data. The detailed results of our system is reported in Table 3.

Final Submission We submitted the ensemble system of the 9 single models after ensemble knowledge distillation stage. The final submission achieves 44.9 BLEU.

4.3 English↔German

For English↔German, we train both directions jointly. We use all parallel data available: Eu-

roparl v10, ParaCrawl v5.1, Common Crawl corpus, News Commentary v15, Wiki Titles v2, Tilde Rapid corpus and WikiMatrix corpus. After data filtering, 28M parallel data remained. We use MosesTokenizer for both English and German. After the pre-processing, a joint BPE vocabulary is learned with 6000 merge operations on the parallel data. We sample parallel data of ratio 80%, 90% and 100% with replacement from all parallel data. Then we train 3 baselines with Transformer Mid 25e6d, Transformer Mid 50e6d and Dynamic Convolution 25e6d architectures respectively, resulting in 9 baseline models. We only employ Newscrawl data as monolingual data for both German and English. The total amount of monolingual data is 90M, containing all Newscrawl 2019 data and others sampled from Newscrawl 2014 to 2018. The 90M data was divided into 9 disjoint parts, each containing 10M sentences, to jointly train 9 systems separately. At the ensemble knowledge distillation stage, we also employ disjoint monolingual data as the distilling data. The detailed results of our system is reported in Table 4.

Table 4: Results of English↔German by sacreBLEU

Fine-tune In this step we use the development sets to handle the domain mismatch problem in WMT. For English→German direction, we fine-tune some of the best single models on news2018 for 1-2 epochs, and then get the final ensemble model from models with fine-tune and models without fine-tune.

Final Submission For either direction, the final submission is an ensemble system from single models with highest BLEU scores on development sets. For the final English→German submission, we replaced the English quote with the German quote. The final submissions on Test20 data achieve 38.2 BLEU for English→German direction and 43.5 BLEU for German→English direction.

4.4 French↔German

For French↔German, we train both directions jointly. The overall parallel data contains 13M sentences available including: Europarl v10, ParaCrawl v5.1, Common Crawl corpus, News Commentary v15, Wiki Titles v2 and WikiMatrix corpus. We train 9 baseline models, each with different architectures (Transformer 15e6d * 2, Transformer Mid 25e6d, Transformer Mid 50e6d, Transformer 15000ffn, Transformer 128hdim, Transformer 256hdim and Dynamic Convolution 25e6d) and each group of three models is combined with 3 different sampling strategies (no sample, up sample 120%, up sample 140%)[3], resulting in 9 single models for each direction. We only employ Newscrawl data as monolingual data for both German and French. The monolingual data contains 90M sentences, including all Newscrawl 2019 data and others are sampled from Newscrawl 2014 to 2018. The data of 90M pairs is divided into 9 disjoint parts, each containing 10M sentences to jointly train 9 systems separately. The detailed experiment results are shown in Table 5.

Final Submission For either direction, the final submission is an ensemble system of all 9 models obtained after the knowledge distillation stage. For the final German→French submission, we replaced the English quote with the French quote. The final submissions on Test20 data achieve 35.7 BLEU for French→German direction and 35.3 BLEU for German→French direction.

up to 8M sentences. We train 9 models with different architectures (Transformer 15e6d * 2, Transformer Mid 25e6d, Transformer Mid 50e6d, Transformer 15000ffn, Transformer 128hdim, Transformer 256hdim and Dynamic Convolution 25e6d) and each group of three models is combined with different sampling strategies (no sample, up sample 120%, up sample 140%) on both directions. We only used Newscrawl as English monolingual data. The English monolingual data contains 90M sentences, including all Newscrawl 2019 data and others sampled from Newscrawl 2014 to 2018. We divide the data into 9 disjoint parts. Since Polish Newscrawl corpus only contains 3M sentences, we additionally employ the Polish common crawl data. We sample 90M sentences from the Polish common crawl data which is then divided into 9 disjoint parts. Each part contains 10M common crawl sentences and 3M Newscrawl sentences. Then we apply the joint training and knowledge distillation as described in Section 3. The detailed experiment results are shown in Table 6.

Final Submission Our final submission is an ensemble system consisting of all 9 models obtained after the ensemble knowledge distillation stage. The final submissions on Test20 data achieve 26.1 BLEU for English→Polish direction and 34.4 BLEU for Polish→English direction.

4.6 English↔Pashto

For English↔Pashto, we used all parallel data containing 13M sentences available as follows: ParaCrawl v5.1, Wiki Titles v2 and the Khmer and Pashto parallel data. For Pashto→English, we fine tune the three pre-trained models on all data with different sampling strategies. Each pre-trained model is fine tuned with three different sampling strategies and we get 9 models. For English→Pashto, we find that the models fine-tuned from the pre-trained models have lower BLEU score than the baseline model trained from scratch, so we use the 9 baseline models which are trained with different architectures and sampling strategies. The English monolingual data has 90M sentences containing all Newscrawl 2019 data and others sampled from Newscrawl 2014 to 2018. We divide the data into 9 groups. The detailed experiment results are shown in Table 7.

Final Submission For Pashto→English, our final submission is an ensemble model consisting of all 9 models obtained after the ensemble knowledge distillation stage. For English→Pashto, we find the ensemble model has lower BLEU score than the best single model, so we use the best single model as our final submission. The final submissions achieve 10.6 BLEU on wmt20 testset for English→Pashto direction and 20.0 BLEU for Pashto→English direction.

4.7 English↔Tamil

Direction	En→Ta	Ta→En
Testset	news20 dev	news20 dev

+mRASP	9.2	17.9
iterative BT	11.8	23.8
BLEU on WMT20 testset submission	7.9	19.7

Table 8: Results of English↔Tamil by sacreBLEU

For English↔Tamil, we use all parallel data containing 533K sentences in total. We use all provided Tamil monolingual data. Following the procedure of English↔German, the English monolingual data contains 90M sentences, including all Newscrawl 2019 data and others sampled from Newscrawl 2014 to 2018. The 90M data was di-

vided into 9 disjoint parts, each containing 10M sentences. For Tamil, we don't apply tokenizer and the raw text is directly split by BPE subword. We fine-tune the three pre-trained models on all parallel data with two different sampling strategies: no sample and up sample 120%, resulting in 6 models. We then conduct back translation for one iteration afterwards, each using one part of the English monolingual data for generating English→Tamil pseudo data, and all Tamil monolingual data for generating Tamil→English pseudo data. The detailed experiment results are shown in Table 8.

Final Submission For both English→Tamil and Tamil→English directions, our final submission is a single model. The final submissions achieve 7.9 BLEU for English→Tamil and 19.7 BLEU for Tamil→English.

4.8 English↔Khmer

Direction	En→Km	Km→En
Testset	news20 dev	news20 dev
Baseline	39.3	12.7
+mRASP	42.8	14.4
iterative BT	46.5	16.9
Ensemble System	-	17.8
BLEU on WMT20 testset submission	51.8	17.6

Table 9: Results of English↔Khmer by sacreBLEU

For English↔Khmer, we used all parallel data containing 4M sentences available as follows: ParaCrawl v5.1 and the Khmer and Pashto parallel data. For Khmer, we extract a dictionary from the Khmer and Pashto parallel data. The km data in this dataset is separated by a special token ǂ00b. Loading this dictionary in the Jieba tokenizer, we get a Khmer tokenizer. We preprocess the Khmer data with our Khmer tokenizer followed by BPE subword. We fine tune the three pre-trained models on all data with different sampling strategies. Each pre-trained model is fine tuned with three different sampling strategies and we get 9 models. We use all provided Khmer monolingual data. The English monolingual data has 90M sentences containing all Newscrawl 2019 data and others sampled from Newscrawl 2014 to 2018. We divide the data into 9 groups. The detailed experiment results are shown in Table 9.

Final Submission For Khmer→English, our final submission is an ensemble model consisting of all 9 models after the iterative back-transkation stage. For English→Khmer, we find the ensemble model has lower BLEU score than the best single model, so we use the best single model as our final submission. The final submissions achieve 51.8 BLEU on wmt20 testset for English→Khmer direction and 17.6 BLEU for Khmer→English direction.

5 Conclusion

This paper describes VolcTrans's NMT systems for the WMT20 shared news translation task. For all directions, we almost adopted the same strategies, except for low-resource language pairs, we employed multilingual pre-training to boost the baseline models. We found that splitting the monolingual data into disjoint parts is an effective way to increase data diversity among single models, which is an important premise for building strong ensemble models. Our final systems achieved significant improvements, usually 3 to 5 BLEU scores, over baseline systems by integrating techniques such as tagged back-translation, iterative back-translation, random ensemble, knowledge distillation.

Abstract

This paper describes Tencent Neural Machine Translation systems for the WMT 2020 news translation tasks. We participate in the shared news translation task on English ↔ Chinese and English → German language pairs. Our systems are built on deep Transformer and several data augmentation methods. We propose a boosted in-domain finetuning method to improve single models. Ensemble is used to combine single models and we propose an iterative transductive ensemble method which can further improve the translation performance based on the ensemble results. We achieve a BLEU score of 36.8 and the highest chrF score of 0.648 on Chinese → English task.

1 Introduction

Recently, Transformer (Vaswani et al., 2017), that depends on self-attention mechanism , has significantly improved the translation quality. It is widely used as basic Neural Machine Translation (NMT) models in previous WMT translation tasks (Wang et al., 2018b; Li et al., 2019; Sun et al., 2019). In this year's translation task, our Tencent Translation team participated in three WMT2020 shared news translation tasks, including Chinese → English, English → Chinese and English → German. For the three tasks, we use similar model architectures and training strategies. Four structures are used and all of them are based on deep transformer which are proven more effective than the standard Transformer-big models (Li et al., 2019).

In terms of data augmentation, we adopt R2L training (Zhang et al., 2019) to all the tasks. Monolingual data is only used in English → German task following the back-translation manner (Sennrich et al., 2016b). Different from the standard back-translation, we add noise to the synthetic source sentence in order to take advantage of large-scale monolingual text. In addition, we add a special token to the synthetic source sentence to help the model better distinguish the bilingual data and synthetic data. The in-domain finetuning (Sun et al., 2019) is very effective in our three experiments and specially, we propose a boosted finetuning method for English ↔ Chinese tasks. We also take advantage of the combination methods to further improve the translation quality. The "greedy search ensemble algorithm" (Li et al., 2019) is used to select the best combinations from single models. Then for English ↔ Chinese tasks we propose an iterative transductive ensemble (ITE) method based on the translation results of the ensemble models. For English → German task, we apply the noise channel model for re-ranking (Yee et al., 2019).

This paper was structured as follows: Section 2 describes the dataset. We present the detailed overview of our system in Section 3. The experiment settings and main results are shown in Section 4. Finally, we conclude our work in Section 5.

2 Dataset

2.1 Chinese ↔ English

The bilingual data used in Chinese ↔ English task includes all the available corpus provided by WMT2020: News Commentary v15, Wiki Titles v2, UN Parallel Corpus V1.0, CCMT Corpus, WikiMatrix, Back-translated news. The Chinese sentences are segmented by jieba segmentor[1] while the English side is processed by Moses tokenizer. We collect 18M sentence pairs after filtering.

2.2 English → German

The bilingual data used in this task includes all the available corpus provided by WMT2020. For the Paracrawl part, We filter most of the data due to

*Equal contribution. Correspondence to {*frostwu*, *brightxwang*, *vinnylywang*, *fangxuliu*}@*tencent.com*.

Proceedings of the 5th Conference on Machine Translation (WMT), pages 313–319
Online, November 19–20, 2020.

bad quality and collect 15M sentence pairs. Totally, 22M sentence pairs are used for training. Both the languages are tokenized by *tokenize.perl* script[2]. Then BPE is applied with 32K operations. The vocabulary is shared with 32K unique words. For monolingual data, we randomly select 80M sentences from NewsCrawl2017-2019 for back-translation and 45M are used for training after filtering

2.3 Data Processing

Pre-processing To pre-process the raw data, we apply a series of open-source/in-house scripts, including full-/half-width conversion, Unicode conversation, punctuation normalization, tokenization and true-casing. After filtering steps, we generated subwords via BPE (Sennrich et al., 2016c) with pre-defined merge operations of 32,000.

Filtering To improve the quality of data, we filtered noisy sentence pairs according to their characteristics in terms of language identification, duplication, length, invalid string and edit distance. More specifically, we filter out the sentences longer than 150 words. The word ratio between the source and the target must not exceed 1:1.3 or 1.3:1. According to our observations, the filtering method can significantly reduce noise issues including misalignment, translation error, illegal characters, over-translation and under-translation.

3 System Overview

3.1 Model Architecture

In our systems, we adopt four different model architectures with TRANSFORMER (Vaswani et al., 2017):

- **DEEP** TRANSFORMER (Dou et al., 2018; Wang et al., 2019; Dou et al., 2019) is the TRANSFORMER-BASE model with the 40-layer encoder.

- **HYBRID** TRANSFORMER (Hao et al., 2019) is the TRANSFORMER-BASE model with 40-layer hybrid encoder. The 40-layer hybrid encoder stacks 35-layer self-attention-based encoder on top of 5-layer bi-directional ON-LSTM (Shen et al., 2019) encoder.

- **BIGDEEP** TRANSFORMER is the TRANSFORMER-BIG model with 20 encoder layers.

- **LARGER** TRANSFORMER is similar to BIGDEEP model except that it uses 8192 as the FFN inner width.

The main differences between these models are presented in Table 1. To stabilize the training of deep model, we use the Pre-Norm strategy (Li et al., 2019). The layer normalization was applied to the input of every sub-layer which the computation sequence could be expressed as: normalize $\rightarrow$ Transform $\rightarrow$ dropout $\rightarrow$ residual-add. All models are implemented on top of the open-source toolkit Fairseq[3] (Ott et al., 2019).

3.2 Data Augmentation

Data augmentation is a commonly used technique to improve the translation quality. There are various of methods to conduct data augmentation such as back-translation (Sennrich et al., 2016a), joint training (Zhang et al., 2018) etc. In this section, we will introduce the methods we used in WMT2020.

3.2.1 Large-scale Back-translation

Back-translation is the most commonly used data augmentation technique to incorporate monolingual data into NMT (Sennrich et al., 2016a). The method first trains an intermediate target-to-source system, which is used to translate target monolingual corpus into source. Then the synthetic parallel corpus is used to train models together with the bilingual data.

In this work we apply the noise back-translations method as introduced in (Lample et al., 2018). When translating monolingual data we use an ensemble of two models to get better source translations. We follow (Edunov et al., 2018) to add noise to the synthetic source data. Furthermore, we use a tag at the head of each synthetic source sentence as Caswell et al. (2019) does. To filter the pseudo corpus, we translate the synthetic source into target and calculate a Round-Trip BLEU score, the synthetic pairs are dropped if the BLEU score is lower than 30. Notably, we only apply back translation to the English $\rightarrow$ German task. We find that back translation decrease the translation quality to Chinese $\leftrightarrow$ English tasks in our experiments.

Embedding Size	512	512	1024	1024
FFN Size	2048	2048	4096	8192

Table 1: Hyper-parameters of different Transformer models used in our system.

3.2.2 R2L Training

The approach is proposed by (Zhang et al., 2019). The main idea is to integrate the information of Right-to-Left (R2L) models to Left-to-Right (L2R) ones. Following this work, we translate the source sentences of the parallel data with both a R2L model and a L2R model, and use the translated pseudo corpus to improve the L2R model. We drop the pseudo parallel data if the BLEU score lower than 15. This method is applied to all the three tasks.

3.3 Finetuning

We use in-domain finetuning to further improve the model performance on news domain as previous study (Sun et al., 2019) shows that finetuning is very effective on the WMT2019 news translation tasks. For the three tasks, the finetuning is slight different and we will introduce them seprately in the following of this section.

Finetuning Zh → En Models For this task, we use all the previous development and test dataset as in-domain corpus D that includes WMT2017 development data, WMT2017 test data and WMT2018 test data. After training an NMT model M with the above methods, we finetune W on D with the same hyper parameters of training M. When testing on the WMT2019 test set, we achieve about 4-5 BLEUs improvement. As the in-domain corpus is very limited, we propose a boosted finetuning method by using the R2L training method to boost the finetuning process, which is named finetuning (boost). In our final submission, we add the WMT2019 test to D, the batch size is set to 2,048, the finetuning finished after 3k training steps.

Finetuning En → Zh Models We select the WMT2017 development data, WMT2017 test data and WMT2018 test data as the in domain corpus D in both tuning models and final submission which is different from Zh → En task. In addition, we do not use R2L training or add WMT2019 test to D, as we find this is useless. When finetuning, we reset the optimizer and use a fixed learning rate of 8e-5. The batch size is set to 1024 and the finetuning finishes after 900 upates.

Finetuning En → De Models We select the document whose source side is originally in English from all previous development and test dataset as in-domain corpus D. Single models are trained with the above methods are then finetune on D for one epoch with a fixed learning rate of 1e-4. In our final submission, the WMT2019 test set is added to D for better performance improvement.

3.4 Re-ranking

We use noisy channel model re-ranking method (Yee et al., 2019). This method is implemented in Fairseq [4]. Three features are used as following:

Source-to-Target Model Instead of a single model, we use the ensemble model as source-to-target model. Four well-trained single models are used. The decoding beam size is set to 25. We collect the log probability of each translation candidates.

Target-to-Source Model The target-to-source model is the channel mode which is used to translate the candidates back to source. We use a big transformer model for target-to-source.

Language Models For language model, we train a small GPT-2 model with FFN=8192 for target monolingual data.

Tuning We use random search to choose values in the range $[0, 3)$ for λ_1 , λ_2 and length penalty. The parameters are tuned on development set.

3.5 Ensemble

Model ensemble is a widely used technique in previous WMT workshops (Li et al., 2019; Sun et al.,

[4]https://github.com/pytorch/fairseq

2019; Wang et al., 2018a) which can boost the performance by combining the predictions of several models at each decoding step. In our work, we use two kinds of ensemble methods and finally the two are combined for further improvements.

3.6 Greedy Based Ensemble

This method is proposed by Li et al. (2019). The method adopts an easy operable greedy-base strategy to search for a better single model combinations on the development set. For more detail, please refer to the original paper. We also train single models with different hyper parameters to ensure the diversity. We refer to this method as **Ensemble** in the following.

3.7 Iterative Transductive Ensemble

Transductive ensemble (TE) is proposed by Wang et al. (2020c). The key idea is that source input sentences from the validation and test sets are firstly translated to the target language space with multiple different well-trained NMT models, which results in a pretranslated synthetic dataset. Then individual models are finetuned on the generated synthetic dataset. We propose an variation of TE, the Iterative Transductive Ensemble (ITE) which is based on Ensemble, as following:

Algorithm 1: Iterative Transductive Ensemble

Input: Single models M_1^m, In-domain corpus D, E_1^n is n different ensemble combinations
Output: Single models M_1^m

Translate D with E_1^n and get ${D'_1}^n$
Train each M_1^m on $D \cup {D'_1}^n$ and get ${M'_1}^m$, then $M_1^m = {M'_1}^m$
$t := 0$
while *not convergence* **do**
    Translate D with M_1^m and get ${D''_1}^n$, then ${D'_1}^n = {D'_1}^n \cup {D''_1}^n$
    Train each M_1^m on $D \cup {D'_1}^n$ and get ${M'_1}^m$, then $M_1^m = {M'_1}^m$
    $t := t + 1$
return ,

4 Experiments and Results

4.1 Setups

The implementation of our models is based on Fairseq [5]. All the single models are carried out on 8 NVIDIA V100 GPUs each of which have 32 GB memory. We use the Adam optimizer with $\beta_1 = 0.9$ and $\beta_2 = 0.98$. The gradient accumulation is used due to the high GPU memory consumption. The batch size is set to 8192 toknes per GPU and the "update-freq" parameter in Fairseq is set to 8. Specifically, for LARGE settings, the batch size is 4096 and "update-freq" is 16. We set max learning rate to 0.0007 and warmup-steps to 4000. All the dropout probabilities are set to 0.1. We select the checkpoint with the lowest loss on development set as the final checkpoint in each training. We calculate sacreBLEU score [6] for all experiments which is officially recommended. The WMT2019 testset (test2019) is used as the development set for all the tasks.

4.2 Chinese → English

Table 2 shows the Chinese → English translation results on validation set. We train multiple single models in each settings and report the best scores in Table 2. The R2L method can significantly improve the baseline by 2.45 BLEU scores. It is surprising to find a gain of almost 5 BLEU improvement on test2019 dataset. After we boost the in-domain corpus, we can achieve 1 more BLEU on the DEEP model. This illustrates that the finetuning is very effective on the WMT2019 test set.

In our experiments, the ensemble models consists of 5 single models: 1 HYBRID, 1 BIGDEEP, 3 LARGER models. As shown in the Table2, the ensemble models outperform the best single model by 1.06 BLEU score. We then apply transductive ensemble to LARGER models and finally the performance achieves 38.99. We also find that the single models that applied TE cannot bring further improvement to ensemble results. We do not apply re-ranking to this task, as we find that the improvement is insignificant. Our WMT 2020 Chinese → English submission achieves a SacreBLEU score of 36.8 and chrF score of 0.649.

4.3 English → Chinese

Table 3 shows the English → Chinese translation results on validation set. We also train multiple single models and report the best scores in the Table. After applying R2L method, we achieve 0.4 to 1 BLEU. We can observe that the improvement from finetuning is not as high as Chinese → English tasks, where only more 1 BLEU is gained. We also find that the boosted finetuning is harmful in this task, thus we omit the results. The ensemble

+reranking	45.9	
+PostProcessing	47.3	

Table 4: BLEU evaluation results on the WMT 2019 English → German test set.

setting consist of 4 models, that are 2 BIGDEEP, 2 LARGER models, which outperform the best single model by 0.74 BLEU.

4.4 English → German

Table 4 shows the results on English → German translation. The baseline is the BIGDEEP model using only bilingual data. R2L training boosts the BLEU score from 41.58 to 43.05. After adding back-translation, we further improve the BLEU score to 44.37. The finetuning can further achieve 0.93 BLEU improvement on the BIGDEEP model.

In this task, the ensemble models consists of 4 single models: 1 DEEP, 2 BIGDEEP, 1 LARGER models. As shown in Table 4, the ensemble models outperform the best single model by 0.4 BLEU score. We then apply noisy channel re-reranking to ensemble results and finally achieve 45.9 BLEU on the development set.

We apply a post-processing procedure. After translating the source-side, we normalize the English quotations appearing in the German translations to German-style quotations. We find this can improve the BLEU score on development set by 1.4 points.

5 Conclusion

This paper presents the Tencent Translation systems for WMT2020 Chinese → English news translation tasks. We investigate various deep architectures to build strong baseline systems. Then popular data augmentation methods such as back-translation and R2L training are used to improve the baselines. We also prove that in-domain finetuning is very effective for news translation tasks especially on Chinese → English task. Finally, we adopt the greed-based ensemble algorithm and propose an iterative transductive ensemble method for further improvement.

It is worth mentioning a number of advanced technologies reported in this paper are also adapted to our systems for biomedical translation (Wang et al., 2020b) and chat translation (Wang et al., 2020a) tasks, which respectively achieve up to 1st and 2nd ranks in terms of BLEU scores.

Abstract

This review depicts our submission to the WMT20 shared news translation task. WMT is the conference to assess the level of machine translation capabilities of organizations in the word. We participated in one language pair and two language directions, from Russian to English and from English to Russian. We used official training data, 102 million parallel corpora and 10 million monolingual corpora. Our baseline systems are Transformer models trained with the Sockeye sequence modeling toolkit, supplemented by bi-text data filtering schemes, back-translations, reordering and other related processing methods. The BLEU value of our translation result from Russian to English is 35.7, ranking 5th, while from English to Russian is 39.8, ranking 2th.

1 Introduction

We participated in WMT20 shared news translation task by building neural translation systems for one language pair and two language directions, from English to Russian and from Russian to English. Our systems are based on the framework of the Transformer neural machine translation model, using many techniques and approaches, including the use of BPE subword segmentation for open-vocabulary translation with a fixed vocabulary, large-scale back-translation,and model ensembling.

Neural machine translation(Bahdanau et al., 2014) has emerged as the most promising machine translation approach in recent years, showing superior performance on public benchmarks. The proposed attention mechanism brought a new revolution in the neural machine translation in most cases, making the overall effect of translation much better than before. Then, the Transformer(Vaswani et al., 2017) that makes full use of the attention mechanism demonstrated outstanding performance and effectiveness. Up to now, most of work uses the structure of Transformer, and its superiority has been widely recognized.

Since the beginning of machine translation research, the translation between Russian and English has been extensively developed.As early as 1954, Georgetown University in the United States under the IBM company completed the English-Russian machine translation experiment with the IBM-701 computer, which opened the prelude of machine translation research. During the period, there are three core technologies, rule-based machine translation, statistical machine translation and neural machine translation. However, as the application field of machine translation became more and more complex, the limitations of various technologies started to become obvious. Due to more application scenarios and higher requirements for accuracy, model optimization problems appeared.

The translation between Russian and English is extremely difficult because their linguistic features are distinguished and the lexical composition and grammatical structure of Russian are more complicated than those of English. In the early period,statistical machine translations were hoped to be implemented through phrase-based methods(Marcu and Wong, 2002) and related techniques for language models and translation models. These methods have solved the Russian-English translation problems to a certain extent. Yet, at the same time, there exists translation problems that are high time cost and poor translation effect.

Since then, the emergence of neural machine translation has brought new developments to Russian-English machine translation. The basic modeling framework for neural machine translation is an end-to-end sequence generation model, a framework and method for transforming input sequences into output sequences. There are two

Proceedings of the 5th Conference on Machine Translation (WMT), pages 320–325

points in the core part. One is to represent the input sequence through the encoder, and the other is to obtain the output sequence through the decoder. In addition, for machine translation, neural machine translation not only includes encoding and decoding, but also uses RNN(Sutskever et al., 2014) or other methods to encode sentence pairs. It also introduces an additional mechanism, the attention mechanism(Luong et al., 2015), to help us to convert sequences. These innovations lead to an increase in translation performance in comparison to earlier models. Later, Transformer appeared, which greatly enhances the neural machine translation performance.

This paper is based on Transformer, a neural machine translation network structure, to develop a two-way evaluation task between Russian and English. Taking into account the language characteristics of Russian and English, we have done appropriate operations in data preprocessing, including removing duplicates, deleting unreasonable sentence pairs, lowercase and Latinization operations, and judging sentence alignment problems, removing the parallel corpus with problems. The filtered parallel corpus is then sent to the model for training and the training results are tested.After getting the trained model, we start to consider using the back-translation operation to augment the data, continuing to filter the generated artificial corpus, and put it into the model training together with the original parallel corpus.

Finally, ensemble(Dietterich, 2000), average and rerank(Shen et al., 2004) operations are implemented on different models to improve the overall performance of the translation system.

2 Background

Neural network machine translation is based on a sequence-to-sequence overall structure consisting of an encoder and a decoder. The encoder converts the source language sentence into an intermediate sequence result, and the decoder converts the intermediate sequence result into a target language sentence. There is also the Attention mechanism to help make the results perform better. In the construction of the overall translation system, we used a lot of excellent methods proposed earlier in the literature.

The basic model used here is Transformer, introduced by(Vaswani et al., 2017) . The transformer is an attention-based structure proposed to deal with tasks that require sequence models, such as machine translation. Traditional neural machine translation mostly uses RNN or CNN as the model base of encoder-decoder, and Google's latest Attention-based Transformer model abandons the inherent formula and does not use any CNN or RNN structure. The model works in high-level parallel process, so training speed is also relatively fast while improving translation performance. But it is still computationally expensive.

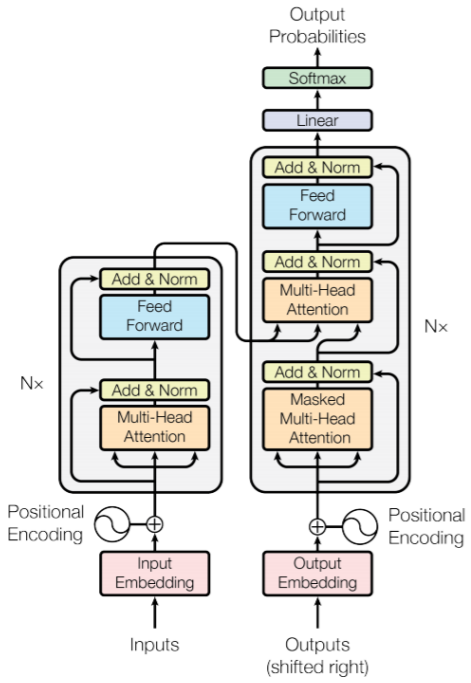

Figure 1: Transformer Structure.

The structure of Transformer is shown in Figure 1. The model is divided into two parts: the encoder and the decoder. The encoder is stacked by six identical layers, each with two more sub-layers. The first sub-layer is a long self-attention mechanism, and the second sub-layer is a simple fully connected feed forward network. A residual connection is added outside the two layers, and then layer normalization is performed. The output dimensions of all sub-layers and embedding layers of the model are d_{models}; the decoder also stacks six identical layers. However, in addition to the two layers in the encoder, the decoder also adds a third sub-layer, as shown in the figure which also uses the residual and layer normalization.

3 Data

We use all available bitext data which provided by WMT for the Russian-English language pair. For the monolingual data we use English and Russian Newscrawl as well as a filtered part of Commoncrawl in Russian. We choose to use Russian Commoncrawl to augment our monolingual data due to the relatively small size of Russian Newscrawl compared to English.

3.1 Data preprocessing

For the Russian-English language pair, we applied a series of preprocessing steps using scripts available in the Moses decoder(Koehn et al., 2007):

- replacing unicode punctuation,
- removing non-printing characters,
- normalizing punctuation,
- tokenization.

Also, we use joint byte pair encodings(BPE) with 32K split operations for subword segmentation(Sennrich et al., 2015) for each language.

3.2 Data Filtering

The large datasets which were crawled from the web would naturally be very noisy. And if they are used in their original and raw format, it may reduce the overall performance of the system. Clearning up these datasets is an important step to achieve good performance on any downstream tasks.

We applied two types of filters for data filtering: one is rule-based heuristics and another are filters based on language identification(Joulin et al., 2016).

For the Russian-English bitext data we used some data preprocessing methods to filter out them including:

- removing the bitext sentence pairs with a fixed length ratio above a certain threshold: for all the datasets we used a threshold of 3.
- removing sentence pairs with too short sentences: for all the sentences pairs we required a minimum number of five words.
- removing sentence pairs with too long sentences: we restricted all data to a maximum length of 100 words.

	En-Ru
No filter	112294588
+ length filter	102154821
+ langid filter	90826580

Table 1: Number of sentences pairs for different filtering schemes.

	En	**Ru**
Newscrawl	33600797	22348032
+ langid filter	32538613	20989583

Table 2: Number of sentences pairs for different filtering schemes.

Through observing the parallel data, we found that there is a surprisingly large amount of text segments in a wrong language in all provided parallel training data. So after some random inspection of the data, it is necessary to apply off-the-shelf language identifiers to the data for removing additional erroneous text from the training data. We apply language identification filtering called langid(Lui et al., 2012)which can classify each sentence in the parallel corpus.

So we can keep only sentence pairs with correct languages on both sides. At last, we filter out about 15% of the original parallel data. See Table 1 for details on the bitext dataset sizes.

For the monolingual English and Russian Newscrawl data we also apply langid filtering. As the monolingual Newscrawl data for Russian is relatively smaller than that of English, we have to augment the Newscrawl data for Russian with monolingual data from commoncrawl corpus.But there is a problem that the quality of commoncrawl corpus is very poor but is also noisy.

4 Experiment

For this evaluation task, we first start from the data preprocessing, through data expansion operations to obtain the data that needs to be trained, and then input the Transformer model for training. We test the training results and finally ensemble results according to the model generated by different strategies, average and rerank operations,for the best results. Next, the specific experiment content will be presented separately. The overall project process is showed in Figure 2.

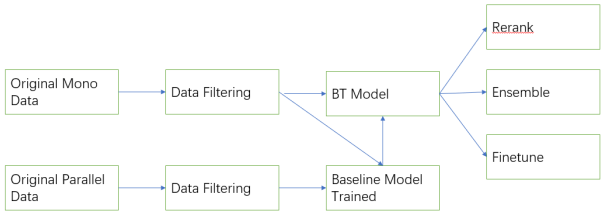

Figure 2: Project Process.

4.1 Base System

Our base system is based on the Transformer architecture (Vaswani et al., 2017) as implemented in Sockeye(Hieber et al., 2017). Due to the time cost and hardware cost of the evaluation task, we choose the basic version of Transformer. The encoder and decoder respectively have 6 sub-layers and the multi-head attention mechanism has 8 heads. The word embedding vector size is 512. We trained all our models using MXNET, which is the deep learning library that Amazon chose. The parameters setting of our models are listed in Table 3.

After the above processing, we use the parallel corpus which provided by the task organizers and direct it into the model for training and testing. The results of the base model can be used to generate reverse translation data to augment the corpus and continue training. The purpose is to maintain the generalization ability and robustness of the model to the greatest extent, and to provide reference for other model training results.

4.2 Large-scale Back-translation

Back-translation(Edunov et al., 2018) is an effective method to improve neural machine translation with monolingual data. It can incorporate monolingual data into a translation system. Firstly,we trained a baseline model that is used to translate monolingual target data into additional synthetic parallel data. This data is used in conjunction with original bitext data the desired source-to-target system.

In this work, due to the training time cost limitation we respectively only selected 10 million Russian and English sentences from the official monolingual corpus for back translation operations. We used back-translations obtained by beam-search(Edunov et al., 2018) from an ensemble of two target-to-source models. We adopt the method to tune the amount of bitext and pseudo-parallel corpora the model is trained on. We found that a ratio of 1:1 synthetic to bitext data can perform the best.

4.3 Fine-tuning

Fine-tuning is a common and effective method to improve machine translation quality especially for a downstream task. When we complete training on the original bitext and pseudo-parallel data, we train an special epoch on a smaller domain-specific data. It can make the model more sensitive to specific domain scenation and then get better results. Here, we select a corpus with much similarity to the test set from the training set to fine-tune the trained model. The similarity scores between the test corpus and the training corpus are sorted and ranked. Then the parallel sentence pairs with higher scores are found and the corpus is extracted as a fine-tuning corpus. In this way, about 5,000 pieces of data are obtained and this part of the corpus is input into the previously trained model to obtain the result of fine-tuning the model, so that it can perform better on the test set.

4.4 Model Reranking

N-best reranking is a method of improving translation quality by scoring and selecting a candidate hypothesis from a list of n-best hypotheses generated by a trained model. Extracting only one of the highest-scoring statements from the translation results of the model as an output is not necessarily the best result. So this strategy can be used to extract the best three from each translation model result as a candidate set. Then use some rules to rerank and get the best one as the output result. The translated content thus obtained is the comprehensive output of multiple results of each model. The rules used here include weighted summation of beam search score and the language model scores. The first one is based on the beam score returned during decoding, but different models have different performances, so it is difficult to sort under a uniform metric. So we introduced different weights for different models. Using beam score weight as the final score for each translation result, the final result was obtained by screening. The second one gives scores of the generated translations using the pre-trained language model. They are judged from the linguistics itself and the sentences with the highest scores are selected. The final result is an output that combines the highest scores of the two methods described above.

The above models also had different batch sizes,

Parameters	Transformer
optimizer	adam
max-num-checkpoint-not-improved	16
num_words	50000:50000
optimized-metric	perplexity
max-seq-len	100:100
loss	cross-entropy

Table 3: The parameters setting of Transformer are implemented by Sockeye .

comparison of the number of graphics cards and vocabulary sizes in the training process. We extracted them for the optimal results. Finally, the output is simply post-processed. In order to comply with common practice in natural language processing. However, due to the limitations of time and hardware resources, not every experiment has been refined and detailed totally, so there is still improvement of results in the future.

4.5 Ensemble Model

Ensemble is a method that combines the results of multiple models. The purpose of this is to complement the advantages of different models, make up for the problems that fall into the local optimum and get the results of the machine translation model with better comprehensive effects. For the sake of simplicity, only different initialization random seed parameters are set for the same model. So training of multiple models is performed, generally two or three models, and finally the results of all models are subjected to ensemble operation. By composing and complementing multiple models, we obtain the comprehensive optimal results of data translation.

5 Results

Results and ablations from Russian to English are shown in Table 4, from English and Russian are shown in Table 5. We report case-sensitive SacreBLEU scores using SacreBLEU(Post, 2018). We report all the case-sensitive BLEU(Koehn et al., 2007) score of our submitted system on this year's test set.

5.1 Russian To English

From Russian to English, we can see that langid filtering and ensembling improve our baseline performance on this year's test set by about 0.7 BLEU. This is perhaps due to the addition of higher quality bitext data and improved data filtering techniques. The addition of back-translated(BT) data

Type of Text	Pair	Bleu	Improve
base-re	RU-EN	33.1	0
filter-re	RU-EN	34.2	+1.1
ensemble-re	RU-EN	36.6	+2.4
fintune-re	**RU-EN**	**39.1**	+2.5
rerank-re	RU-EN	38.2	-1.1

Table 4: Russian-English Experiment Result.

Type of Text	Pair	Bleu	Improve
base-re	EN-RU	23.1	0
filter-re	EN-RU	24.2	+1.1
ensemble-re	EN-RU	24.5	+0.3
fintune-re	**EN-RU**	**24.8**	**+0.3**
rerank-re	EN-RU	24.6	-0.2

Table 5: English-Russian Experiment Result.

improves single model performance by about 0.3 BLEU, combining this with fine-tuning and ensembling gives us a total of 3 BLEU. We composed two models which have different random seeds and then re-trained on the fine-tuning corpus. Finally, applying reranking on top of these strong ensembled systems gives another 1.4 BLEU.

5.2 English To Russian

From English to Russian, we observe similar trends to Russian to English, with langid filtering and ensembling improving performance of a baseline system by 1.6 BLEU. Back-translatoin adds 1.5 BLEU, again mostly likely due to the lower quality bitext data available. Also we composed two models which have different random seeds and then re-trained on the fine-tuning corpus. Fine-tuning, ensembling, and reranking add almost 3 BLEU, with reranking contributing 1.2 BLEU.

6 Conclusions

This paper describes our submission to the WMT20 news translation task. In the evaluation task, we es-

tablished a Russian-English bidirectional machine translation system based on Transformer. For translations between Russian and English, we use the same strategy of filtering bitext data, performing beam-search back-translation on monolingual data. Then we train strong individual models on a combination of this data. Each of these models is fine-tuned and ensembled into a final system that is used for decoding with model reranking. In the final list, we got 2th in Ru-En, and 5th in En-Ru. Good results have been obtained in limited time and hardware resources, which is also in line with the industry's demands for service construction. In the whole experiment process, we also gained a lot of experience in data processing and experimental design, which will be of great help in later research and study. We will continue to improve the previous experiments, strive to get better results, and see what rankings can eventually be achieved, in preparation for the next year.

Abstract

This paper describes the DeepMind submission to the Chinese→English constrained data track of the WMT2020 Shared Task on News Translation. The submission employs a noisy channel factorization as the backbone of a document translation system. This approach allows the flexible combination of a number of independent component models which are further augmented with back-translation, distillation, fine-tuning with in-domain data, Monte-Carlo Tree Search decoding, and improved uncertainty estimation. In order to address persistent issues with the premature truncation of long sequences we included specialized length models and sentence segmentation techniques. Our final system provides a 9.9 BLEU points improvement over a baseline Transformer on our test set (newstest 2019).

1 Introduction

The WMT2020 Shared Task on translating news data from Chinese into English provides a challenging test for machine translation systems and an ideal domain for researchers to evaluate new techniques. The DeepMind submission to the constrained data track is based on the modular noisy channel document translation architecture advocated by Yu et al. (2020). In this formulation, the posterior probability of a translation is the product of the unconditional probability of the output document (the language model) and the conditional probability of the translation from the output to source (the channel model). By assuming sentences within a document are independently translated, we can train the channel model using readily available parallel sentences, rather than being reliant on less numerous parallel documents, and the language model on monolingual documents. This modular approach allows the components of the system to be implemented and optimized independently while at inference time, when we reason over the posterior distribution of translations given the source document, conditional dependencies between translations are induced by the language model prior.

The core of our document-level translation architecture is the noisy channel reranker. It requires proposal, channel, and language models, each of which is optimized separately using different techniques and approaches. For the proposal and channel models we use Transformer models (Vaswani et al., 2017) (§4.1) with data augmentation (§4.2), such as back translation (Edunov et al., 2018), distillation (Kim and Rush, 2016; Liu et al., 2016), and forward-translated parallel documents. We further improve these sequence-to-sequence (seq2seq) models by fine-tuning them with in-domain data (§4.3). To improve the robustness of the reranker we apply adversarial training and contrastive learning methods for uncertainty estimation (§4.4). Finally, we include candidate translations generated by Monte-Carlo Tree Search (MCTS) (§B) in order to improve the diversity of the candidate pool for the reranker. Our language models are based on the Transformer-XL architecture (Dai et al., 2019) and optimized with distillation and fine-tuning with in-domain data (§5).

During development, we observed weaknesses in our system's translations for long sentences, largely due to premature truncations. We developed several techniques to mitigate this issue such as sentence segmentation (breaking sentences into logical complete segments) and training specialized models with synthetically constructed long sequences to generate additional proposals for our reranker (§A).

Experiments show that the aforementioned techniques are very effective: our system outperforms the Transformer baseline by 9.9 BLEU points on our test set (newstest2019). Our final system achieves a BLEU score of 35.4 on the

*Equal contribution.

Chinese→English news test set of WMT2020.

2 Document Translation via Bayes' Rule

Following Yu et al. (2020), we model document translation via Bayes' rule. We define $\boldsymbol{X} = (\boldsymbol{x}_1, \boldsymbol{x}_2, \ldots, \boldsymbol{x}_I)$ as the source document with I sentences, and similarly, $\boldsymbol{Y} = (\boldsymbol{y}_1, \boldsymbol{y}_2, \ldots, \boldsymbol{y}_J)$ as the target document with J sentences, where $\boldsymbol{x}_i$ and $\boldsymbol{y}_j$ denote the ith sentence in the source document and the jth sentence in the target document respectively. We assume that $I = J$.

The translation of a document $\boldsymbol{X}$ is determined by finding the document $\hat{\boldsymbol{Y}}$, where $p(\hat{\boldsymbol{Y}} \mid \boldsymbol{X})$ is maximal.

$$\begin{aligned}\hat{\boldsymbol{Y}} &= \arg\max_{\boldsymbol{Y}} p(\boldsymbol{Y} \mid \boldsymbol{X}) \\ &= \arg\max_{\boldsymbol{Y}} \underbrace{p(\boldsymbol{X} \mid \boldsymbol{Y})}_{\text{channel model}} \times \underbrace{p(\boldsymbol{Y})}_{\text{language model}} . \end{aligned} \quad (1)$$

We further assume that sentences are independently translated, and that the sentences within a document admit a left-to-right factorization according to the chain rule. Therefore, we have

$$\hat{\boldsymbol{Y}} \approx \arg\max_{\boldsymbol{Y}} \prod_{i=1}^{|\boldsymbol{Y}|} p(\boldsymbol{x}_i \mid \boldsymbol{y}_i) \times p(\boldsymbol{y}_i \mid \boldsymbol{Y}_{<i}), \quad (2)$$

where $\boldsymbol{Y}_{<i} = (\boldsymbol{y}_1, \ldots, \boldsymbol{y}_{i-1})$ denotes a document prefix consisting of the first $i-1$ target sentences.

The advantages of this formulation is that during training the translation models can be learned from parallel sentences and monolingual documents which are vastly available in practice unlike parallel documents. During test time, when a source document is observed, conditional dependencies between the translation of the source sentences are created in the posterior.

2.1 Reranking

Because of the global dependencies in the posterior distribution, decoding in the aforementioned document translation model is computationally expensive. Following Yu et al. (2020), we use an auxiliary proposal model $q(\boldsymbol{y} \mid \boldsymbol{x})$, that approximates the posterior distribution using a direct model, to focus our search on promising parts of the output space. We then carry out the reranking process using an iterative beam search, over candidates generated by the proposal model q, to optimize the objective:

$$\begin{aligned}\mathcal{O}(\boldsymbol{X}, \boldsymbol{Y}_{<i}, \boldsymbol{y}_i) = {} & \lambda_1 \log p_{\text{PM}}(\boldsymbol{y}_i \mid \boldsymbol{x}_i) + \\ & \lambda_2 \log p_{\text{AM}}(\boldsymbol{y}_i \mid \boldsymbol{x}_i) + \\ & \lambda_3 \log p_{\text{CM}}(\boldsymbol{x}_i \mid \boldsymbol{y}_i) + \\ & \log p_{\text{LM}}(\boldsymbol{y}_i \mid \boldsymbol{Y}_{<i}) + \\ & \lambda_4 |\boldsymbol{y}_i| + \\ & \mathcal{O}(\boldsymbol{X}, \boldsymbol{Y}_{<i-1}, \boldsymbol{y}_{i-1}), \end{aligned} \quad (3)$$

where p_{PM} is the proposal probabilities model, p_{AM} is the adversarially trained proposal model (§4.4.1), p_{CM} is the channel model (§4.4.2), p_{LM} is the language model (§5.1), and $|\boldsymbol{y}|$ denotes the number of tokens in the sentence $\boldsymbol{y}$. The weights of component models (λs) are hyperparameters to be tuned in experiments.

In practice, we generate for each source sentence $\boldsymbol{x}_i$ in the document $\boldsymbol{X}$, a series of *candidates* $\boldsymbol{y}_i$, using the proposal model q. As all of the terms in the objective, except for p_{LM}, only involve independent target sentences, they can be computed ahead of time in a *scoring* phase. The *scored candidates* are then passed to the reranker, where the language model is evaluated on the successive prefixes explored by the search, and which outputs the final document $\hat{\boldsymbol{Y}}$.

Iterative beam search The algorithm starts with k complete documents using randomly selected candidates for each of the source sentences. We then iterate through every source sentence $\boldsymbol{x}_i$, replacing the randomly picked initial candidate with every available candidate $\boldsymbol{y}_i$. We pick the top k scoring *complete* documents and continue iterating over the document. Unlike traditional beam search used by Yu et al. (2020), we go through every sentence in the document multiple times, until the top 1 translation converges (usually 2 to 4 full iterations). This allows for context from latter sentences in the document to inform the choice of earlier candidates.

Iterative beam search found improvements in the model objective over traditional beam search in 63% of the documents in our test set. Improvements in objective did not translate in a stable improvement in BLEU or META scores (Eqn. 4) – in fact those scores were slightly reduced for a number of documents. Nevertheless, an informal human evaluation of translated documents showed preference for iterative beam search.

Selection of the hyperparameters λ We perform a grid search over the hyperparameters λ to

maximize a metric on the validation set. The metric we use is the following META score, combining corpus-level BLEU, TER, METEOR, and the 0.1-quantile of per-document BLEU, such that:

$$\begin{aligned}(1-\text{META})^4 = \text{TER}\times \\ (1-\text{BLEU})\times \\ (1-\text{METEOR})\times \\ (1-q_{0.1}(\text{BLEU})).\end{aligned} \quad (4)$$

When several configurations of hyperparameters achieve values of META very close to the maximum (within 0.02), we pick the one maximizing BLEU and/or minimizing the L_2 norm of the λs, considered as a vector. This corresponds to an intuitive prior towards giving more weight to the language model.

3 Training Data

To train all of the models used in our system, we made use only of the constrained data provided to shared task participants. In this section, we discuss the preprocessing and normalization techniques we carried out in an attempt to reduce spurious uncertainty in the modeling problem.

Text preprocessing We carried out the following text normalization steps prior to use in any models:

- Text normalization. Unicode canonicalization (NKFD from), replacement of common multiple encoding errors present in training data, standardization of quotation marks into "directional" variants, conversion of any traditional Chinese characters into simplified forms. Replacement of non-American spelling variants with American spellings using the aspell library.[1]
- Segmentation into words. Chinese was segmented into word-like units using the Jieba segmentation tool.[2] Punctuation was split from English words using a purpose-built library. These processes were not completely invertible, but they could be undone with simple rules so as to generate presentation-ready English and Chinese.
- True-casing. Words containing only an initial capital letter that occurred at the start of a sentence were replaced with the capitalized variant that occurred most frequently in other positions of the English monolingual training data. Thus, in the previous sentence the initial token would have been *words* rather than *Words*.

Subword units To encode text into sub-word units, we used the `sentencepiece` tool (Kudo and Richardson, 2018). For seq2seq models (i.e., the channel model and proposal models), we trained the segmentation model on the first 10 million sentences of the parallel training corpus,[3] using joint source and target unigram (Kudo, 2018) subword segmentation algorithm with a target vocabulary of 32K tokens and minimum character coverage of 0.9995, which resulted in 32,768 word pieces.[4] For the language model, we used the English side alone with the same vocabulary size and a character coverage of 1.0.

4 Proposal and Channel Models

The proposal model, used to generate candidate translations, and the scoring models (proposal probability model, adversarially-trained proposal model, channel model), used to compute features for the reranker, are seq2seq models. We describe here how we train and use them.

4.1 Sequence-to-Sequence Model

All our models are based on the Transformer architecture (Vaswani et al., 2017). We increased the inner dimension of the feed-forward network from 4,096 to 8,096 and decreased the model size (d_{model}) from 1,024 to 512, which allowed us to use 12 layers with 16 attention heads each. Additionally, we tied the source and target embedding layers. Following (Vaswani et al., 2018), we applied layer normalization to the input of every sublayer as opposed to its original placement after the element-wise residual addition. We used different dropout values for different components: 0.1 for the multi-head attention, 0.05 in the feed-forward network, and finally 0.3 after the sub-layer. Learning rate schedule and dropout were found using the Batched Gaussian Process Bandits (Desautels et al., 2014) algorithm as implemented by Vizier (Golovin et al., 2017). All other hyperparameters

[2] `https://github.com/fxsjy/jieba`

[3] NC followed by CWMT, WikiTitles and UN.

[4] We tried both larger vocabulary sizes and separate vocabularies but neither of these led to an improvement for our system.

were decided upon using grid search. During training, we used a maximum sequence length of 96. For decoding, we used beam search with beam size 6, and set the length penalty alpha to 0.8, and a maximum decoding length of 384. Multi model ensembling was done via softmax output averaging as described in (Freitag et al., 2017).

4.2 Data Augmentation

In this section, we introduce how we augment data based on the given bilingual data and monolingual data. When we train the proposal and channel models, we use all the augmented data along with the original bilingual data.

Back-translation We perform back-translation from monolingual English data using fine-tuned channel models (English→Chinese) with top-k sampling following (Edunov et al., 2018) with $k = 50$ during decoding. We used the same in-domain monolingual data as described in §5.2. We score the back-translated data with fine-tuned proposal (Chinese→English) models, and filter them based on the quantiles of length ratios, sequence log-probability and cross-entropy between one-hot empirical translations and logits from the scorer model. The filtering helped to reduce the size of data from 43.4M to 29.9M paired sentences.

Forward translation to generate synthetic parallel documents We applied a version of our system to monolingual Chinese documents from Gigaword to get synthetic English documents. We only kept documents having between 4 and 25 sentences, we rejected outliers according to their probabilities under the language model, the channel model, and to the overall objective. These were then used to train subsequent versions of the forward (Chinese→English) models.

Data distillation We use knowledge distillation (Kim and Rush, 2016) to do distillation on the original dataset. Specifically, we translate the source-side of the bilingual data using previously trained proposal models (including Right-to-Left (Liu et al., 2016) and Left-to-Right models) and generate distilled candidates. The generated sentences are filtered if BLEU scores are below 30 (Wang et al., 2018; Sun et al., 2019). We then train models on the filtered data along with the original bilingual data and back-translation data. We repeat this process three times using models trained on newly generated data from the previous iteration. We empirically do not find Right-to-Left models significantly differ from Left-to-Right models in performance. Qualitatively we find that distilled data correct few errors in the original bilingual data.

4.3 Fine-tuning

Fine-tuning with in-domain data has been an effective approach for improving translation quality as shown by existing work (Sun et al., 2019; Ng et al., 2019). After training the proposal models with the mix of real and synthetic parallel data, we fine-tuned the models with CWMT and a subset of *newstest2017* and *newstest2018* which were not used for validation.

4.4 Improving Uncertainty Estimation

To improve the robustness of noisy channel reranking, we explore two approaches for improving uncertainty estimation of the seq2seq scoring models.

4.4.1 Adversarially Trained Proposal Models

To simulate different wordings and noises in source and candidate sentences, we follow Cheng et al. (2019) to train the models on noisy adversarial inputs and targets. We use bidirectional language-models to provide the noisy candidates and select the candidates with highest loss (i.e., adversarial source-target inputs). During the training, we optimize the original loss with clean source-target pairs, the language model losses for source and target sides, and the adversarial loss using adversarial source-target inputs. In the final scoring, we use an ensemble of eight adversarially trained models with few differences from Cheng et al. (2019): (a) We explore training with and without the language model losses. Though the models trained without the language model loss generate quite noisy sentences, we empirically find this approach still helps the overall performance. (b) In addition to using the clean hard-labels for the noisy source-target pairs for the adversarial loss as in the original work, we explore a variation using a KL loss between the adversarial source-target logits and the clean source-target logits. We find this variant also improves the overall performance.

4.4.2 Contrastive Channel Models

When scoring candidates, we want the channel models to be sensitive to translation noise (dropped words, permutation, or blanked words) (Edunov et al., 2018). Hence, we develop contrastive training (Yang et al., 2019; Welbl et al., 2020) to train

the models such that it will be more robust in estimating the channel probabilities. Specifically, we use n-gram Transformers (Chelba et al., 2020) with the contrastive loss:

$$\max\left\{\log p(\tilde{\boldsymbol{x}} \mid \boldsymbol{y}) + \eta - \log p(\boldsymbol{x} \mid \boldsymbol{y}), 0\right\}, \quad (5)$$

where $\tilde{\boldsymbol{x}}$ denotes a noisy version (random word deletion, blank, or permutation) of $\boldsymbol{x}$, and $p(\tilde{\boldsymbol{x}} \mid \boldsymbol{y})$ is the perturbed loss term. We ensemble 8 models with a few variants for final channel model scoring. These variants consist of the followings: (1) We use $\eta = \{0.01, 0.001\}$. (2) We use n-gram transformer with $n = 2, 8$. (3) We use models with perturbing source sentences $p(\tilde{\boldsymbol{x}} \mid \boldsymbol{y})$ and models with perturbing target sentences $p(\boldsymbol{x} \mid \tilde{\boldsymbol{y}})$. (4) Instead of using the contrastive loss, we include two models trained to minimize the perturbed loss terms directly. (5) Unlike Yang et al. (2019), where the authors firstly train with the maximum likelihood objective and then finetune with the contrastive loss, we find it empirically works better to train models with linearly increased weights (increasing from 0 to 1 during training) to the contrastive loss (Eq. (5)) along with the original negative log likelihood loss.

4.5 Filtering Candidate Translations

After obtaining candidate translations from strong proposal models, we filter out candidates with length ratio outside of $[e^{-1}, e^{1}]$, or which do not end with end-of-sentence punctuation when the source does, or with more than 4 consecutive identical tokens, or which are excessively compressible, indicating repeated contents, according to the following. We learn a piece-wise linear ordinary least squares model of the zlib-compressed length of true English sentences from their uncompressed length in UTF-8, using the English side of the training data. We then reject candidates the actual compressed length of which is more than 12 standard deviations below their predicted compressed length.

5 Language Model

In this section, we describe the architecture of the language models we used and how we trained them.

5.1 Model

The auto-regressive document language model is a Transformer-XL (Dai et al., 2019), with attention memory length of 512. Following Rae and Razavi (2020), we also used 4-layer blocks of short and long (128-128-128-512) attention memories, capturing short-range correlations in the earlier layers and long-range correlations in the later ones. This led to a 20% speedup of training, and helped the model generalize better to the validation set. We also used knowledge distillation in our Transformer-XL model with a setup similar to Born Again Neural Networks (BANN) (Furlanello et al., 2018), where we regularize the original loss function with term based on the cross-entropy between the new models outputs (student) and the outputs of the original (teacher) model.

Model	Train Data	Fine-tuning	PPL
Transformer-XL	Raw	No	29.4
Transformer-XL	In domain	No	27.4
+ memory + BANN	In domain	No	26.7
+ memory + BANN	In domain	Yes	24.3

Table 1: Language model perplexities per token on the validation set

Let $\mathcal{L}$ denote cross entropy loss function, $\boldsymbol{y}$ one-hot encoded label, $\boldsymbol{s}$ and $\boldsymbol{t}$ outputs of the student and teacher model respectively, then the BANN loss is defined as follows:

$$\mathcal{L}_{\text{BANN}} = \sum_{i=1}^{T} \mathcal{L}(\boldsymbol{y}_i, \boldsymbol{s}_i) \; + \lambda \cdot \mathcal{L}(\boldsymbol{t}_i, \boldsymbol{s}_i). \quad (6)$$

We trained our student network on the loss function in Eqn. 6 and found that $\lambda = 1$ had the best validation perplexity.

5.2 Data

The English data used to train our language models was prepared as described in §3.

In-domain document data for LM training We found that training LMs on a subset of training data that was more closely aligned with the validation set vastly improved the perplexity on the validation and test sets ($\approx 10\%$). To select a well-aligned subset of training data, we ranked the training data according to TF-IDF similarity with each validation document and collected the top 1,000 documents for each validation query together, to form our training data for the LM training. We also tried mixing this sub-sampled in-domain data with the raw data using different weights (essentially equivalent to up-weighting the in-domain data) and found that using purely in-domain data outperformed all other mixing schemes in terms

System	BLEU
Big Transformer	28.1
+ Data augmentation (§4.2)	33.6
+ Fine-tuning (§4.3)	35.8
+ Ensembling (§4.1)	36.6
+ Reranking (§2.1)	37.2
+ Length-targeting improvements (§A)	38.0

Table 2: SacreBLEU scores on newstest2019 Chinese-English.

of held-out perplexities and thus, the in-domain data became our training dataset. As an auxiliary benefit, the model trained on the in-domain dataset (340K iterations) also converged much earlier than the one trained on the raw dataset (500K iterations).

Similar to the sequence model fine-tuning outlined in §4.3, we also fine-tuned our trained language model in order to align the model more closely with the language constructs and domain information in our test data. Table 1 shows the perplexity numbers on the validation set obtained by different train data and model variants described above on the validation dataset.

6 Experiments and Results

We use the original Chinese subset of *newstest2017* and *newstest2018* as our validation set and *newstest2019* as our test set.

The candidate translations for the reranker are generated by 8 ensemble models (6 from each).

Table 2 presents the results of our models on the test set. We report case-sensitive SacreBLEU scores (Post, 2018). Both data augmentation and fine-tuning significantly improve the performance. Ensembling and noisy channel reranking gives about 0.8 and 0.6 BLEU boost, respectively. Finally, our specialized methods for handling long sequences (described in §A) yield a further 0.8 BLEU improvement.

In our final submitted system, we tune the weights of component models and the hyperparameters of sentence segmentation models using a combination of our validation set and test set. For the candidate translations of the reranker, apart from the existing 48 proposals generated by 8 ensemble models, we include additional 48 proposals generated by 8 ensemble models which are fine-tuned with CWMT, newstest2017, newstest2018, and newstest2019. We also include translations generated by MCTS decoding (§B) in our non-primary system. We find that adding a feature marking the length of source sentences longer than 60 words helps the reranker handle long sentences better. We therefore include this feature in addition to proposal probability, adversarial proposal probability, channel probability, language model probability, and length bonus (Eqn. 3).

Our system achieves a 35.4 BLEU score on newstest2020.

7 Conclusion

This paper describes the DeepMind submission to the WMT2020 news Chinese-English translation task. Using the noisy channel model (Yu et al., 2020) as our core document translation system, we optimized its component models using data augmentation, fine-tuning with in-domain data, MCTS decoding (§B), and knowledge distillation. We also addressed premature termination in long sentences by training specialized length expert models and segmenting long sentences into multiple shorter sentences (§A). We have demonstrated the marginal contributions of these methods in our analysis and our final system comprising all these methods outperforms the Transformer baseline by 9.9 BLEU points on newstest2019.

In the appendix, we additionally include the description of our specialized methods for handling long sequences and the MCTS decoding algorithm. The candidate translations generated by MCTS decoding are added to the candidate pool of the noisy channel reranker in our non-primary system.

A Length Considerations

The WMT Chinese evaluation data presents documents as a sequence of segments. These segments are sentence-like units that were delimited in the original article by either unambiguous structural transitions, such as the end of a headline, or unambiguous end-of-sentence punctuation (.!?). However, in some contexts, a complete Chinese sentence may be ended with a comma (Xue and Yang, 2011). This leads to disproportionately more segments in the evaluation data being multi sentence than in the training data, which consists primarily of paired sentences, phrases, and words. Since generalization from short sequences to longer ones is a weakness of neural sequence to sequence models (Lake and Baroni, 2018), to ensure that our candidate pool contains adequate translations of long sentences, we had special handling for long sequences.

A.1 Length Analysis

There is a strong linear relationship between the number of Chinese words in the source segment and the number of English words in the translation (Figure 1 Left). The translations from our initial system were able to match this relationship when the source segment contained less than 60 words. After this point, the translations became too short. Inspection of these translations showed that the primary cause of failure was emitting the EOS token too early. Since the translations were good up to the point of truncation, we focused on methods to prevent early termination. Our final pool consisted of candidates from our original proposal models only for sentences that had less than 80 words and the rest were generated from the techniques outlined here.

A.2 Length Experts

We trained a number of length expert models with a sequence length of 384 tokens. As few ($\leq 1\%$) sentences in the training data were longer than our default sequence length, we used a mixture of real parallel data, synthetic data as described in §**??**, and concatenation of consecutive synthetic sentences to train these length experts. In addition, we also used the original proposal models which were further fine-tuned with long sequences($\geq$ 60 tokens) as additional length experts. These specialized models to handle longer sentences were used to generate proposals for sentences between 60 and 100 words.

A.3 Sentence Segmentation

We found that a lot of the long ($\geq$ 60 words) sentences in our dataset had complete sentences concatenated with commas, semicolons, full-stops, exclamations and question marks. While the latter ones are all conclusive end of sentences, commas are ambiguous as an end of sentence. Hence, we built a comma classifier that distinguished commas that signify end-of-sentence from the normal commas. While training data for this classifier was generated as outlined in (Xue and Yang, 2011), our classification model had feed-forward layers on top of the Transformer encoders (further fine-tuned on this task) that we trained for our translation task. During inference time, we recursively split every sentence on standard end-of-sentence punctuation and then semicolons followed by terminal commas (as determined by the comma classifier), into reasonably sized segments (10-60 words); Very short segments ($<$ 10 words) were merged with their neighboring segments. After this first wave of splits, if long segments ($\geq$ 60 words) still persisted, we further split them recursively on all colons, commas and reverse commas into segments between 40-60 words. Each segment was then translated independently using our translation models. This segmentation procedure was used to generate proposals for all sentences that had more than 60 space-separated words.

Sentence remerging model For each split of a sentence, we obtain a list of candidate translations, and need to combine this. For n splits with k translations each, we have k^n translations in total. Provided n and k are reasonable, we can enumerate these, but it is still too many candidates to present directly to our global reranker, so we need to have a "local" reranker that will select the best k' of these.

To select these, we define a reranking model in terms of our usual features (language model log probability for the remerged sentence to ensure coherence, channel log probabilities for the remerged candidate, sum of the direct translation log probabilities for each segment, and the total length). We

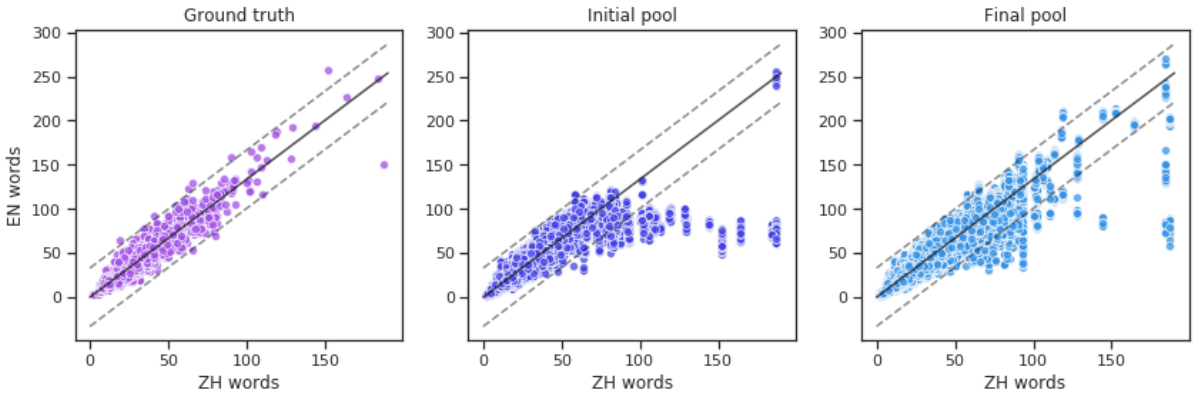

Figure 1: Relationship between the number of white space separated words on normalized text translation pairs. Left is the ground truth for our validation and test datasets. Middle is our initial candidate pool for this data while Right is our pool including candidates from length expert models and our segmentation technique. The black line is the maximum likelihood fit under $|\boldsymbol{y}_i| \sim \mathcal{N}(\beta \cdot |\boldsymbol{x}_i|, \sigma)$ with the dotted grey dashed lines representing the 3σ bounds.

select the remerged candidates k' maximizing an approximate lower bound of the corpus-BLEU.

Approximation to BLEU The weights of the features are learned so as to minimize an approximation to the expected negative log BLEU score. For the reference sentence $\boldsymbol{y}$ and hypothesis $\hat{\boldsymbol{y}}$, the negative expected log BLEU score is defined as:

$$\mathcal{L} = -\mathbb{E}\Big[\min\{0, 1 - |\boldsymbol{y}|/|\hat{\boldsymbol{y}}|\} + \sum_{i=1}^{4} \log c_i(\hat{\boldsymbol{y}}, \boldsymbol{y}) - \log r_i(\boldsymbol{y})\Big],$$

where c_i is a function that counts the clipped i-gram matches against a reference, and r_i counts the i-grams in a reference (Papineni et al., 2002).

Although our model assigns probabilities independently to sentences, BLEU is defined on an entire corpus, and because of the nonlinear functions in BLEU, we cannot compute this expectation tractably. We therefore approximate it by moving the expectations inside the nonlinear functions:

$$\mathcal{L} \approx -\Big[\min\{0, 1 - |\boldsymbol{y}|/\mathbb{E}[|\hat{\boldsymbol{y}}|]\} + \sum_{i=1}^{4} \log \mathbb{E}[c_i(\hat{\boldsymbol{y}}, \boldsymbol{y})] - \log r_i(\boldsymbol{y})\Big].$$

In this approximation, the corpus-level expectations for i-gram counts and the length can be computed tractably using the linearity of expectation. To obtain a learning algorithm, we differentiate this quantity with respect to the weightings of the scoring models and perform gradient descent.

Even with our small number of features, this objective has many local optima and in practice we run the optimizer starting from different positions and find a solution that obtains a high BLEU score and highly weights the language model (during development, we noticed that a higher weight to LM probabilities corresponded to noticeably more fluent translations, even if there was little difference in BLEU).

B MCTS Candidates

The candidate pool generated by the sequence to sequence model optimize the search space that is favorable according to those models and may fail find certain translations that score poorly according to sequence to sequence models, but receive high scores from the noisy channel model. In order to include such translations into the candidate pool, we employ Monte Carlo Tree Search (MCTS), to optimize the noisy channel objective directly. MCTS does not require a partial translation evaluation function, as opposed to Beam Search, making it an appropriate choice for decoding non-factorizable objective functions.

We define the translation environment as a progressive left-to-right language generation process, where each state $s_{\boldsymbol{y}}$ defines a sequence of tokens $\boldsymbol{y}$, and each action a_w appends a word type w at the end of the sequence generating a new state $s_{\boldsymbol{y}'}$. When an action appends the end of sentence token, a terminal state is generated. The reward R for terminal states corresponds to a log-linear combi-

nation of model scores $\phi \in M$ as follows:

$$R(s_{\boldsymbol{y}}) = \exp\left(\sum_{i \in M} \lambda_i \phi_i(\boldsymbol{y})\right), \qquad (7)$$

where λ denotes the weights attributed to each of the models. Our MCTS decoder is composed of two optimization processes running simultaneously. The former aims at finding the optimal state $R(s_{\boldsymbol{y}})$ for each of the sentences in the validation and test sets. The latter maximizes the correlation between the BLEU score on the validation set by optimizing the weights λ.

B.1 Monte Carlo Tree Search with Log Linear Models

MCTS decodes a sentence by growing a search tree. Each node in the tree corresponds to a state but adds additional statistics in order to optimally expand the search tree. Expansion is achieved by applying actions to existing nodes in the tree, generating child nodes. The search process starts with a tree with root node, which corresponds to an empty translation, and gradually expands the tree by append new words to existing nodes in the tree.

Each MCTS iteration performs the following four steps: **selection**, **expansion**, **simulation** and **backpropagation**.

The **selection** step aims at choosing the most likely node in the tree to generate the optimal translation. We employ a standard criteria UCT (Upper Confidence Bounds for Trees (Kocsis and Szepesvri, 2006)), which selects nodes recursively starting from the root according to the following criteria:

$$\text{UCT}(s) = Q(s) + b\sqrt{\frac{2 \ln N(s')}{N(s)}},$$

where s denotes the current node and s' is the parent node. $N(s)$ denotes the number of times s was traversed by the selection process and $Q(s)$ denotes the average reward obtained from s in the $N(s)$ traversals. b is a constant that quantifies the trade-off between exploitation and exploration. We set it to $b = 1$ in our experiments.

In general the average value $Q(s)$ is computed by accumulating the reward $V(s)$ obtained one any traversals containing s, then computing $Q(s) = \frac{V(s)}{N(s)}$. However, as our reward function (Eqn. 7) is concurrently updated by optimizing the weights λ, we store the accumulative individual scores $V_i(s)$ of each of the models ϕ_i. Prior to a MCTS iteration, we update λ and compute $Q(s)$ as follows:

$$Q(s) = \frac{\exp(\sum_{i \in M} \lambda_i V_i(s))}{N}.$$

This allows changes to the weights to be directly reflected in the entire search tree without the recomputation of any tree statistics. As for models M, we trained 9 proposal models and 7 channel models with the architecture defined in §4.1, and 8 language models with the architecture defined in §5.1.

Once a node s is selected, a new child s' is added to the tree in the **expansion** step.

The **simulation** step attempt to compute the expected reward for s'. This is generally accomplished by performing multiple random rollouts starting from state s', where actions are sampled from an uniform distribution until a terminal state is found. These states are then scored according to Eqn. 7. The estimate of the expected reward of s' is computed as the mean of the scores of different rollouts. However, the sparsity underlying natural language generation and the computational complexity of the scoring function makes this practice computationally challenging. Rather than performing multiple rollouts that sample from an uniform distribution at each timestamp, we perform a single rollout that runs greedy decoding starting from the translation prefix defined from state s'. As it is computationally expensive to perform decoding for each MCTS iteration, use a light-weight proposal model trained on the same data, but with a simpler architecture. For this purpose, we reduce the architecture described in §4.1 into a single layer seq2seq layer with 128 hidden units. While this network underfits the data, we found that this trade-off is desirable as it reduces the large dimensionality of the vocabulary to the few examples that are sensible at each prefix leading to a significant speed-up. The quality of the found translation remains unaltered as the reward is still computed with the full models.

Finally, each of the model scores $V_i(s')$ is propagated to all nodes from the root to s' in the **backpropagation** step.

B.2 Pairwise Reranking Optimization

In order to optimize the weights λ in Eqn. 7, we we employ the weight optimization method for log-linear models described in (Hopkins and May, 2011), which allows us to optimize our log-linear

model with respect to the non-differentiable objective function that is BLEU. This method, denominated as PRO, approximates the objective function by training a binary classifier, such that two translations $\boldsymbol{y}$ and $\boldsymbol{y}'$ respect the following equality:

$$g(\boldsymbol{y}) > g(\boldsymbol{y}') \Leftrightarrow \sum_{i \in M} \lambda_i(\phi_i(\boldsymbol{y}) - \phi_i(\boldsymbol{y}')) > 0,$$

where g is the objective function, namely BLEU. Thereby, this requires the generation of pairs $\boldsymbol{y}$ and $\boldsymbol{y}'$, where the LHS property holds. These samples are then used as data to train the model defined in the RHS.

We generate the data by sampling from the MCTS tree for each sentence pair in the development set. As $Q(s)$ is the expected score of a log-linear model with probabilities as components ϕ, we expect that $Q(s)$ is bounded in the $[0, 1]$ interval. Thus, at node s', the probability of sampling child s is given by $\frac{Q(s)}{\sum_{c \in C(s')} Q(c)}$, where $C(s)$ denotes all children of node s'. Once a leaf node is found, if it's terminal we sample its translation, otherwise we sample the translation obtained from its rollout.

Both MCTS search and PRO optimization are executed in parallel, as the former needs optimal weights in order to optimally grow the search tree, and the latter needs the search tree to generate candidates. Thus, at each iteration, the PRO optimizer samples from the most updated version of the tree for each data point in the development set, and updates the set of weights λ, which are then used in the subsequent MCTS iterations.

Abstract

This paper describes NiuTrans neural machine translation systems of the WMT20 news translation tasks. We participated in Japanese↔English, English→Chinese, Inuktitut→English and Tamil→English total five tasks and rank first in Japanese↔English both sides. We mainly utilized iterative back-translation, different depth and widen model architectures, iterative knowledge distillation and iterative fine-tuning. And we find that adequately widened and deepened the model simultaneously, the performance will significantly improve. Also, iterative fine-tuning strategy we implemented is effective during adapting domain. For Inuktitut→English and Tamil→English tasks, we built multilingual models separately and employed pretraining word embedding to obtain better performance.

1 Introduction

This paper describes the NiuTrans submissions to the WMT20 news tasks, including English→Chinese (EN→ZH), Tamil→English (TA→EN), Inuktitut→English (IU→EN) and Japanese↔English (JA↔EN) five directions and all of our systems were built with constrained data sets. Some useful methods in the WMT18 (Wang et al., 2018) and WMT19 (Li et al., 2019) submissions are also reused this time, such as model ensemble, knowledge distillation (KD) et al., and we explore some novel approaches this year.

For this participation, we experimented with some deeper and wider Transformer (Vaswani et al., 2017) architectures to get reliable baselines, nucleus sampling (Holtzman et al., 2020) in back-translation to generate more suitable pseudo bilingual sentences, more effectively fine-tuning strategy to adapt domain. Particularly in the low-resources tasks, {TA,IU}→EN, we built multilingual neural machine translation by using some similar language to get better performance and further replaced decoder's word embedding by an English pretraining Transformer language model's which trained by two monolingual in-domain data corpora.

Furthermore, we presented a new fine-tuning pattern which could significantly improve the BLEU score on the test set, and it worked well on all five tasks whether it is a low or rich resource. We carefully rethought this strategy and found the main gain came from domain adaptation and improved inferior translations.

Our systems and this paper followed six main steps:1) data preprocessing and filter, 2) iterative back-translation to generate pseudo bilingual data, 3) using different model architectures to enhance the diversity of translation, 4) iterative knowledge distillation by in-domain monolingual data, 5) iterative fine-tuning with in-domain using small training batch, 6) translation post-process.

2 System Overview

2.1 Data Preprocessing and Filtering

For EN→ZH and JA↔EN tasks, we first normalized the punctuation in Chinese and Japanese monolingual data by using Moses (Koehn et al., 2007) `normalize-punctuation.perl` script. English and Inuktitut sentences were segmented by Moses, while Chinese, Japanese and Tamil used NiuTrans (Xiao et al., 2012), MeCab[1] and IndicNLP[2] separately for word segmentation. After converting numbers and punctuation into English pattern, and then we normalized English words in Japanese sentences to Japanese by using Sudachi (Takaoka et al., 2018).

As previous work (Wang et al., 2018) indicated that it's important to clean data strictly, so this year

Proceedings of the 5th Conference on Machine Translation (WMT), pages 338–345
Online, November 19–20, 2020.

we used a stricter data filter scheme than Li et al. (2019) and the rules were following:

- Filter sentences length ratio lower than 0.4 or upper than 3 and punctuation ratio more than 0.3.
- Remove sentences that have the long word which consist of more 40 characters or words more than 200.
- Remove repeated n-gram translation and repeated sentences except for IU.
- Filter out the sentences whose alignment scores obtained by fast-align are lower than -6.
- Detecting language and delete other languages or have a special HTML label.
- Filter sentences in which parentheses on both sides do not correspond.
- Use Unicode to filter sentences that other characters more than 10.

And when we cleaned monolingual data still employed those rules and particularly there were some lines which include two or more sentences, we write a script to cut them into several sentences.

2.2 Iterative Back Translation

Back-translation is an effective way to boost translation quality by using mono data to produce pseudo training parallel data. Also, it can alleviate domain adapted problems by carefully choosing the in-domain target data. As Edunov et al. (2019); Bogoychev and Sennrich (2019) stated, due to the test target side only consisted of manual translations, back translation didn't bring evident BLEU increase on the test set. Despite our experiments proved that the deeper architectures still showed apparent improvements as the number of data increases.

As Li et al. (2019) stated, it's crucial to select in-domain mono data for back-translation. After picking out English mono data, we first used 50 million news data to train a language model (LM) built with Transformer structures, then ranked cleaned mono data which scored by trained language model before. However, it's hard to find massive in-domain data for other languages to train a neural LM, so the better choice was using a statistical method, in here we selected XenC toolkit[3] (Rousseau, 2013). The in-domain data consisted of the valid set source side and News Commentary high-quality mono data. For avoiding the short sentence ranked too high, each score was multiplied by a length penalty when using both approaches to score these data.

We chose a sample base model as our back-translation model rather ensemble model which may gain a little improvement, but needed spending huge decoding time. For multilingual model back-translation, we followed Johnson et al. (2017)'s work adding a target language label in the source side, so translations could be adapt to the target language.

This year we also followed previous work Edunov et al. (2019) and we added a new pseudo data produce methods–Nucleus Sampling, according to Holtzman et al. (2020)'s work. For all tasks we participated in, we first employed the beam search approach to generate the best translations as pseudo data and the scale of the pseudo was about 1:1 to real data. Then merge those data to retrain model and do back-translations again. Repeated those steps until the valid set BLEU have few increases then stop iterative back-translation processing. Notably, during the second back-translation, for EN→ZH task we used topk sampling and the k is 10 following last year, while for JA↔EN tasks, nucleus sampling method which the p was set 0.9 preferred better comparing topk, whereas for other tasks, {TA,IU}→EN, simply sampling was better.

2.3 Multilingual Model

For TA→EN and IU→EN, building a multilingual model is a simple and effective way to boost performance because of knowledge transfer. For TA→EN task, we added six other similar languages and only one language Russian (RU) for IU→EN task, because there were no other languages witch a relationship with IU. For TA, We up-sampled the TA data then shuffled all the train data so that each training batch could have TA data with high-probability. As for IU, we only added 0.3 million RU high quality data, then we directly merged two languages as training data. To enhance the effect of transfer learning, we utilized only one model which all the language shared the same parameters including word embeddings and vocab. Bilingual data were reused to fine-tune the model for adapting parameters to the target language after model convergence.

Table 1: Transformer Architectures.

2.4 Model Architectures and Ensemble

Inspired by deep network Wang et al. (2019), we tried to use simple deep, or deep and wide network architectures based on the Transformer to explore the relationship of performance and model parameters. We mainly carried out experiments on the structures of the model in Table 1. And we kept six decoder layers unchanged because it only could gain a few improvements tough many model parameters increased.

Deep Network: This model structure simply changes encoder layers, hidden size and other hyper-parameters based on vanilla Transformer.

DLCL Network: For a deeper network, we employed DLCL (Wang et al., 2019) to get more diverse models.

Filter size: This hyper-parameter represents the dimension size of feed-forward network (FFN) and simply increasing this could bring some improvements (Wang et al., 2018; Sun et al., 2019; Bawden et al., 2019). Notably, when using the deep Transformer architecture, the training time and model parameters will increase sharply with the augment of the FFN size.

RPR and relative length: The relative position representation (RPR) (Shaw et al., 2018) improves self-attention by adding relative position information. The relative length which we set 8 is the key parameter of this method.

For choosing models to ensemble, we utilized the ensemble search method which used a script to traverse all possible combinations then recorded the best one. For JA↔EN, we chose 6 of 10 while other tasks were 4 of 10.

2.5 Iterative KD and Fine-tuning

Sun et al. (2019) showed the self-learning strategy is a very effective approach to improve performance when the test set only composed of manual translations and we mainly reused (Li et al., 2019) iterative KD strategy to implement self-learning. Specifically, we designed a new iterative fine-tuning process which consists of three steps: 1)using ensemble models to decode valid and test source side sentences then fine-tune models with those pseudo data, 2) fine-tune with the valid set by a small training batch and learning rate, 3) self-learning with in-domain data which chose by only test source side. Repeat these steps two or three times according to the increase of the valid score in the third step. Figure 1 shows these steps. Notably, for being consistent with the composition of the test set, we picked out the data that the source side is real while the target side is manual from the previous valid set. In this way, we found that iterative fine-tuning can promote news title translation quality.

2.6 Reranking

For JA↔EN tasks, we followed the Ng et al. (2019), using a neural language model, and a reverse translation model. Different from the last year, we used several length penalties to generate more candidates.

2.7 Post Editing

For tasks to the English side, we only confirmed the numbers whether to generate correctly by designing a rule-based script which generated two lists for source and target sentences separately. For EN→ZH, the strategy was the same as the last year Li et al. (2019) and particularly dealt with the name's translation by using rules to delete the English name copy in Chinese sentences. For EN→JA task, we transferred English punctuation to Japanese pattern.

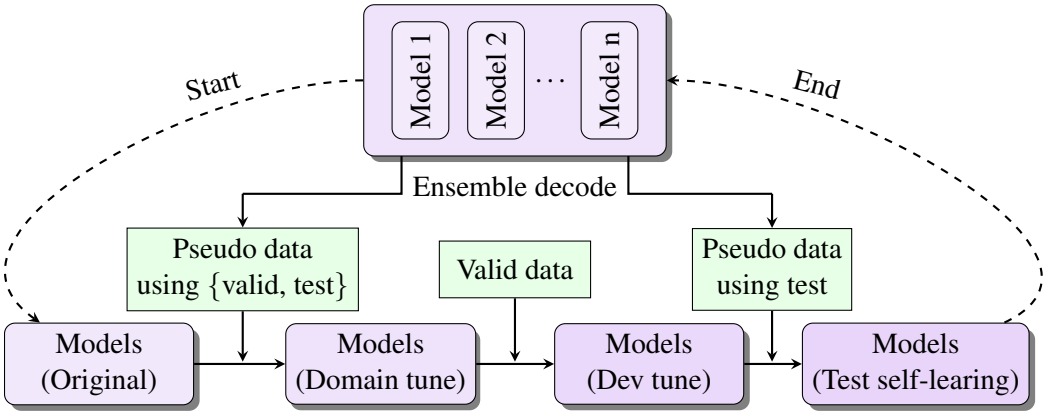

Figure 1: Iterative fine-tuning process

3 Experiment

3.1 Experiment Settings

For all tasks, we implemented the Transformer-Base as our baseline and all of our architectures were pre-normalize Wang et al. (2019) for stable training except Transformer-Big. We implemented models based on Fairseq (Ott et al., 2019) and trained on eight 2080Ti GPUs. We used Adam optimizer (Kingma and Ba, 2014) during training, $\beta_1 = 0.9$, $\beta_2 = 0.997$ for pre-normalize architectures and training batch was 2048 token while we accumulated gradient 4 times for achieving bigger batch size. We shuffled the training data before generate training batch and the training batch each epoch, so we didn't consider the document information. The max learning rate and warmup-steps we set were 0.002 and 8000 separately for deep models but 0.0016 and 16000 for deep and wide models. During training, we used fp16 to accelerate training with few performance damage. Training 15 epoch was enough for most Tasks, while 20 epoch was better for EN→ZH task and we implemented Li et al. (2020)'s methods to accelerate training. To get more robust models, the last 5 checkpoints were saved every 5000 steps for EN→ZH and JA↔EN tasks but every epoch for TA→EN,IU→EN tasks were average ensemble. During back-translation, we followed Hu et al. (2020)'s approaches to accelerate decoding when generating pseudo data.

3.2 JA↔EN Results

For JA↔EN tasks, we chose ParaCrawl v5.1, New Commentary v15, WikiMatrix, Japanese-English Subtitle Corpus, The Kyoto Free Translation Task Corpus, TED Talks total six parallel data corpus about 14.35 million and News crawl, News Commentary, Common Crawl , TED Talks 4 Japanese monolingual data corpus about 1.7 billion. After the data filter, 12 million parallel data was left and 11 million selected by the neural language model was used as training data. Cleaning several billion low-quality monolingual data will cost too much time, so here we shuffled all the data then split it into dozens of parts, one of which was 20 million. Finally we used total eight of them, each piece was carefully cleaned. Before we also used BPE (Sennrich et al., 2016) models with 32,000 merge operations for both sides to reduce UNK size in vocabulary.

We implemented back-translation two times, the first was beam search while the second was Nucleus Sampling to generate translations. Each time we selected 12 million mono data sampled from all the remaining data. Tough the second time didn't increase significantly compared with the first time, the performance was further improved with the increase of the model parameters. Considering the training time, we finally chose 35 million training data on both sides. Notably, as the official stated that the test target side only consists of manual translations, so the back-translation didn't bring too many improvements, only +0.55 and +2.1 BLEU separately in two tasks.

In order to get more diverse models for ensemble and achieve better results, we trained total 10 models including that eight with different architectures which have been shown in Table 1 and other two with different training data which consisted of 11 million bilingual data and 12 million pseudo data produced by the first back-translation. Then we searched from all the models to find the best combination of 6 out of 10 models. And Table 2 showed that the ensemble is still a robust and effective way

System	JA→EN Valid	JA→EN Test	EN→JA Valid	EN→JA Test
Baseline	19.9	20.4	33.2	34.8
+ 12M Beam	21.0	20.8	36.5	36.8
+ 12M Nucleus	21.2	21.0	36.7	36.9
Deep15-filter-768-RPR	23.2	22.9	39.1	39.3
+ Iterative KD	24.4	24.6	39.8	40.1
+ Iterative fine-tuning	25.6	26.2	40.7	41.6
+ Ensemble	25.8	26.5	41.1	41.9
+ Post Edit	26.4	26.6	42.1	42.8

Table 2: BLEU scores on JA↔EN tasks

to boost translation quality.

We implemented iterative KD process twice and each time chose 0.3 million monolingual data using ensemble model to decode then trained 3 to 5 epoch according to the dev PPL. Then we iteratively fine-tuned the models three and two times for JA→EN and EN→JA separately. And interestingly in some real case, the translation of the news titles was significantly improved after iteratively fine-tuning.

As Table 2 shows, iterative KD and fine-tuning strategies could significantly increase the BLEU on the test set.

We used the reranking model like Ng et al. (2019), though it could boost 0.3 BLEU on dev set, it didn't get benefits on the test set. During post edit, we mainly checked the number according to the source side, it also could on EN→JA task.

3.3 EN→ZH Results

In EN→ZH task, we employed News Commentary v15, UN Parallel Corpus V1.0, Back-translated news, CCMT Corpus total four corpora, and after data filter, 10 million data were sampled to train out baseline model. We set wmt18 and wmt19 test as the valid set and mainly referred wmt19 set. In the back-translation, 10 million mono data were sampled from News crawl, News Commentary and Common Crawl three corpora then used the baseline model decode by beam search strategy during the first time. During the second time, we still utilized the same amount of pseudo data while topk sampling which the k is 10 were used to translation mono sentences. From Table 3, we could find that back-translations didn't perform well. Finally 30 million data in total were used to train 10 models, different from other tasks, here we searched the best two combinations of 4 out of 10 models for iterative KD strategy to ensure the diversity of models.

System	news2019	news2020
Baseline	35.4	40.8
+ 10M Beam	36.3	41.6
+ 10M TopK	36.1	41.5
Dlcl25-RPR	38.7	44.2
+ Iterative KD	39.4	45.4
+ Iterative fine-tuning	39.8	45.9
+ Ensemble	40.1	46.7
+ Post Edit	40.3	47.3

Table 3: BLEU (%) scores on EN→ZH task

Then we implemented three times iterative KD and each time sampled 10 million in-domain source data. Table 3 showed that it's a very effective method to get 0.8 improvements. Furthermore, we fine-tuned models iteratively three times to domain adaptation and improved +0.5 BLEU. Due to implementing two ensemble combinations to decode sentences, at last model ensemble was still effective to gain 0.8 improvement. According to the WMT19 test, we adjusted the name's translations pattern during the post edit step then resulting in a 0.6 BLEU performance increase.

3.4 IU→EN Results

In IU→EN task, we only used Nunavut Hansard Inuktitut-English Parallel Corpus 3.0 total 1.3 million sentences. After the data filter, 1.1 million data was left to build the baseline model. Though romanization Inuktitut data directly was not effective, it performed better than baseline when build a multilingual system by adding 0.3 million Russia data which has the most similar semantic with Inuktitut. After that, we implemented data augmentation

System	Valid	Test
Baseline	29.6	21.3
+ Romanization	29.3	21.0
Multilingual baseline	30.2	21.6
+ 1.3M Beam	30.6	22.2
+ 1.3M Sampling	30.9	22.2
Deep15-filter-768-RPR	32.5	23.5
+ Knowledge Distillation	32.5	25.4
+ Iterative fine-tuning	49.3	28.4
+ Ensemble	49.3	28.6
+ Post Edit	49.7	29.1

Table 4: BLEU (%) scores on IU→EN task

System	Valid	Test
Baseline	12.8	13.2
Multilingual baseline	14.2	15.1
+ 0.5M Beam	19.2	15.7
+ 1M Beam	20.9	16.6
Deep15-filter-768-RPR	22.8	19.0
+ Knowledge Distillation	23.4	20.6
+ Iterative fine-tuning	23.6	20.7
+ Ensemble	23.8	21.0

Table 5: BLEU (%) scores on TA→EN task

by using the multilingual model to back-translate mono data iteratively twice and each time using 1.1 million data which equaled the true training sentences. Interestingly, the bigger and wider models improved translation quality distinctly proving it's a robust way whether the training data is rich or not.

Then we first fine-tuned the multilingual model to the target language by using 1.1 million bilingual data several epochs. According to the valid source set, ensemble models were used to decode monolingual in-domain 0.1 million data which was chosen by XenC and gained 1.85 BLEU improvement. Then fine-tuned models only once, because different from the bilingual model, the multilingual model didn't perform very well during the fine-tuning stage.

Finally we selected four models to ensemble and gained 0.18 increase, because different models were too similar after fine-tuning. And we fixed the punctuation and the score improved 0.52 BLEU. During the post process, we fixed the number and punctuation translation.

3.5 TA→EN Results

The Ta→EN task is similar to IU→EN but more complicated, because more data corpus and language can be used to build the multilingual system. Specifically, we total used {Hindi (HI), Kannada (KN), Malayalam (ML), Punjabi (PA), Telugu (TE), Urdu (UR)}→EN total six other languages, 17 million sentences according to Kudugunta et al. (2019)'s work showed similar languages with TA. From Table 5, it can be seen that using similar languages to build a multilingual system can indeed improve the performance. Also, using iterative back-translation is still an effective way but couldn't add too much pseudo language data because this will make the real target language data account for the whole data was too small, which leaded to performance damage. During the back-translation process, due to too many languages in one model, we followed Johnson et al. (2017)'s approach to build a reverse model to ensure translation quality.

For the model architectures we used, the wide and deep model was still very effective and improved 2.33 BLEU comparing with the base model. Also it performed better than simple deepen model layers. After finishing KD and fine-tuning, finally gain 1.92 improvements.

4 Conclusions

This paper introduced our submissions on WMT20 five tasks and our main exploration is using more diversified architectures, improving a iterative fine-tuning strategy and utilizing several similar languages to build a multilingual model on low-resource tasks. And we experimented with iterative back-translation by different decoding strategies, using pre-trained embeddings in multilingual models. On the whole, all of our systems performed competitively and ranked 1st on JA↔EN both sides.

Abstract

This paper describes a test suite submission providing detailed statistics of linguistic performance for the state-of-the-art German-English systems of the Fifth Conference of Machine Translation (WMT20). The analysis covers 107 phenomena organized in 14 categories based on about 5,500 test items, including a manual annotation effort of 45 person hours. Two systems (Tohoku and VolcanTrans) appear to have significantly better test suite accuracy than the others, although the best system of WMT20 is not significantly better than the one from WMT19 in a macro-average. Additionally, we identify some linguistic phenomena where all systems suffer (such as idioms, resultative predicates and pluperfect), but we are also able to identify particular weaknesses for individual systems (such as quotation marks, lexical ambiguity and sluicing). Most of the systems of WMT19 which submitted new versions this year show improvements.

1 Introduction

Fine-grained evaluation has recently had increasing interest on several natural language processing (NLP) tasks. Focusing on particular issues gives the possibility to analyse the automatic output in ways that cannot be seen by generic metrics. This is of particular importance in the era of deep learning, which has led to high performances and differences that are relatively difficult to distinguish. Additionally, detailed evaluation can provide indications for the improvement of the systems and the data collection, or allow focusing on phenomena of the long tail that might be of particular interest for certain cases (e.g. social biases; Stanovsky et al., 2019).

The most common method for fine-grained or focused evaluation are the *test suites* (also known as *challenge sets* or *benchmarks*; Guillou and Hardmeier, 2016; Ribeiro et al., 2020). These are test sets engineered in a particular way, so that they can test the performance of NLP tasks on concrete issues (Müller et al., 2018; Bawden et al., 2018).

This paper is presenting the use of such a test suite for the evaluation of the 11 German→English Machine Translation (MT) systems that participated at the Shared Task of the Fifth Conference of Machine Translation (WMT20; Barrault et al., 2020). The evaluation applies the DFKI test suite on German-English, via 5,514 test items which cover 107 linguistically motivated phenomena organized in 14 categories. After a reference in related work (Section 2), we explain shortly the structure of the test suite (Section 3) and present the results (Section 4) and the conclusions (Section 5).

2 Related Work

The use of test suites was introduced along with the early steps of MT in the 1990's (King and Falkedal, 1990; Way, 1991; Heid and Hildenbrand, 1991). With the emergence of deep learning, recent works re-introduced test suites that focus on the evaluation of particular linguistic phenomena (e.g. pronoun translation; Guillou and Hardmeier, 2016) or more generic test suites that aim at comparing different MT technologies (Isabelle et al., 2017; Burchardt et al., 2017) and Quality Estimation methods (Avramidis et al., 2018). The test suite track of the Conference of Machine Translation has already taken place two years in a row, allowing the presentation of several test suites, focusing on various linguistic phenomena and supporting different language directions. These include work in grammatical contrasts (Cinkova and Bojar, 2018), discourse (Bojar et al., 2018), morphology (Burlot et al., 2018), pronouns (Guillou et al., 2018) and word sense disambiguation (Rios et al., 2018). When compared to the vast majority of the previous test suites, the one presented here is the only one

that performs a systematic evaluation of more than one hundred phenomena on the state-of-the-art systems participating in WMT20.

3 Method

The test suite is a test set that has been devised manually with the aim to allow testing the MT output for several linguistic phenomena. The entire test suite consists of subsets that test one particular phenomenon each, through several test items. Each test item of the test suite consists of a source sentence and a set of correct and/or incorrect MT outputs. At the evaluation time, the test items are given as input to the MT systems and it is tested on whether the respective MT output consists a correct translation. By observing the amount of the test items that are translated correctly, one can calculate the performance of the MT systems regarding the respective phenomenon.

The evaluation presented in this paper is based on the DFKI Test Suite for MT on German to English, which has been presented in Burchardt et al. (2017) and applied extensively in the WMT shared task of 2018 (Macketanz et al., 2018) and 2019 (Avramidis et al., 2019). The current version includes 5,560 test items in order to control 107 phenomena organised in 14 categories. Some sample test items can be seen in Table 1 whereas a more detailed list of test sentences with correct and incorrect translations can be found on GitHub[1].

3.1 Application of the test suite

The construction of the test suite has been thoroughly explained in the papers from the previous years (Avramidis et al., 2018, 2019) and depicted in Figure 1 (steps *a*-*c*). The test items of the test suite are given as input to the MT systems (step *d*). Their MT outputs are tested using a set of rules (regular expressions or fixed strings), each rule specific for a phenomenon, that defines whether the translations are correct with respect to the tested phenomenon (step *e*). When the automatic application of the rules cannot lead to a clear decision on whether the translation is correct or not, the test item is left with a warning. The warnings are consequently resolved by human annotators with linguistic knowledge, who inspect the MT output, provide a clear judgment and also augment the set of the rules to cover similar cases in the future (step *e*).

For every system we calculate the phenomenon-specific translation accuracy as the the number of the test sentences for the phenomenon which were translated properly, divided by the number of all test sentences for this phenomenon:

$$\text{accuracy} = \frac{\text{correct translations}}{\text{sum of test items}}$$

Each phenomenon is covered by at least 20 test items[2], whereas the same test items are given to multiple systems to achieve comparisons among them. In order to achieve a fair comparison among the systems, only the test items that do not contain any warnings for any of the systems are included in the calculation.

In order to define which systems have the best performance for a particular phenomenon, all systems are compared with the system with the highest accuracy. When comparing the highest scoring system with the rest, the significance of the comparison is confirmed with a one-tailed Z-test with $\alpha = 0.95$. The systems whose difference with the best system is not significant are considered to be in the first performance cluster and indicated with boldface in the tables.

3.2 Experiment setup

In the evaluation presented in the paper, MT outputs are obtained from the 11 systems that are part of the *news translation task* of the Fifth Conference on Machine Translation (WMT20). These are 6 systems submitted by the shared task participants, one baseline system from the shared task of the biomedical domain (WMTBiomedBaseline; Bawden et al., 2020) and 4 online commercial systems whose output has been obtained by the workshop organizers and therefore have been anonymized

[1] https://github.com/DFKI-NLP/TQ_AutoTest

[2] with the exception of 7 phenomena which have 9-19 items

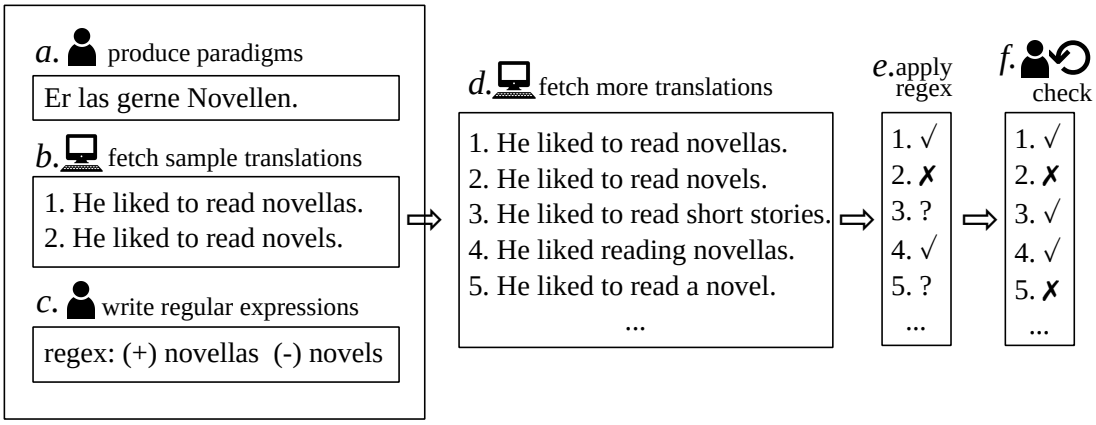

Figure 1: Example of the preparation and application of the test suite for one test sentence

(Online-A, B, G and Z). The submitted systems are OPPO (Shi et al., 2020), PROMT (Molchanov, 2020), Tohoku-AIP-NTT (Kiyono et al., 2020), UEdin (Germann, 2020), VolcTrans (Wu et al., 2020) and Zlabs, whereas a 7th system under the name "yolo"was ignored because it contained arbitrary translations. Unfortunately, contrary to previous years, very few system descriptions were provided by the time this paper was written and it is therefore not possible to associate linguistic performance with system types and settings.

As explained earlier, the application of the test suite on the output of the 11 systems left about 10% of unresolved warnings which needed to be manually edited. A human annotator with linguistic background devoted about 45 working hours in order to resolve 99% of them (resulting into 5,514 valid out of 5,560 total items).

4 Results

The accuracy of each system per linguistic category is briefly shown in Table 5 whereas the detailed statistics depicting the accuracy for every linguistic phenomenon, grouped in the respective linguistic categories are shown in Table 7. Since every category and every phenomenon have a different amount of test items, the average scores, shown in the last rows of the tables, are computed in three different ways: The first aggregates the contributions of all test items to compute the average percentages (micro-average), the second (Table 5) computes the percentages independently for each category and then takes the average (hence treating all categories equally; *category macro-average*) and the third (Table 7) computes the percentages independently for each phenomenon and then takes the average (hence treating all phenomena equally; *phenomenon macro-average*). The significantly best systems for every category or phenomenon are bold-faced.

Very high scores do not necessarily mean that the MT of the respective grammatical phenomenon has been solved, but rather that the current test items of the test suite (which was engineered with the emergence of the first neural MT systems in 2017) are unable to expose difficulties of the systems. The artificial nature of the test suite and the variable number of test items per category and phenomenon should also be taken in consideration when doing comparisons between categories and phenomena.

4.1 Comparison between systems

Two systems are standing out for their overall performance. **Tohoku** achieves the best category macro-averaged accuracy of 88.1%, whereas it is sharing the first position with **VolcTrans** based on their micro-averaged accuracy (85.3-85.4%). The systems UEdin, Online-B, Online-G and Online-A are next. Tohoku and VolcTrans are also the best performing systems for all linguistic categories, whereas UEdin is losing in one category and Online-A is losing in two categories.

Two systems, WMTBiomedBaseline and ZLabs show very low performances and are assumed to be non state-of-the-art systems. We will therefore exclude these two systems from the discussion and conclusions for phenomena and categories. Whereas no description was available for ZLabs, the lower performance of the WMTBiomedBaseline can be attributed to the fact that it was trained with only 56% of the parallel training data used by Tohoku and no synthetic data. Among the rest of the systems, the worst performing one is Online-Z, achieving the lowest accuracy (74% on both micro- and macro-average), being on par with the best systems

Verb Valency	
Ich erinnere mich seiner.	
I remember his.	fail
I remember him.	pass
False Friends	
Er las gerne Novellen.	
He liked to read novels.	fail
He liked to read novellas.	pass

Table 2: Examples of linguistic categories with lower accuracy with passing and failing MT outputs

on only 6 categories.

BLEU scores (Papineni et al., 2002) on the official test-set are also calculated for further comparison. The order of the systems based on BLEU seems to correlate with the order given by the category macro-average with the exception of one system (OPPO). Since BLEU scores are calculated on a different test set, further investigation is needed to confirm if this correlation is of any significance. According to the official human evaluation campaign (Barrault et al., 2020, table 11), the first nine systems are tied, so it is hard to compare this system order with theirs.

4.2 Linguistic categories

The average accuracy regarding the linguistic categories ranges in relatively high numbers, between 68.9% and 97.3%. The categories with the highest accuracy in average are the **negation** (97.3%), the **composition** (85.3%), the **subordination** (85.3%) and the **named entinties and terminology** (82%). The ones with the lowest accuracy are the **multiword expressions** (MWE), the **ambiguity**, the **false friends** and the **verb valency** (68.9-71.5%).

When one tries to identify weaknesses of particular systems, OPPO is suffering mostly concerning function words and long distance dependencies (LDD) / interrogatives. Online-Z and PROMT have issues with ambiguity and several systems have issues with punctuation. Some of these issues are discussed in a more fine-grained level below.

The comparison of the state-of-the-art systems with the low-resource WMTBiomedBaseline indicates that some categories, such as ambiguity and composition, are particularly sensitive to low resources, as their accuracy is proportionally lower than other categories if compared to the respective category accuracies of the state-of-the-art systems.

Table 2 contains examples from the two low accuracy categories *verb valency* and *false friends*. *Verb valency* refers to the arguments that are being controlled by the predicate. Certain verbs require a specific grammatical case. In our example, the German verb *sich erinnern* (to remember) requires a genitive object, in this case *seiner*. *Seiner*, however, can also mean *his* as in the possessive pronoun, which explains the mistranslation of *I remember his*.

False friends are words in different languages that look similar and are therefore often mistaken for being translations of one another, even though their meanings differ. The German noun *Novelle* does not translate to *novel*, but to *novella* or *short story*. While you would expect a human to make these kind of translation errors, it is surprising to see that also MT systems are prone to mistranslating false friends.

4.3 Linguistic phenomena

The accuracy regarding individual linguistic phenomena has a wide range, between very low scores (15%) and full success (100%). The phenomena which all systems had difficulty to handle were the **idioms** and the **resultative predicates**, with most systems scoring only 20% and 26% respectively. However, the overall performance on these phenomena has improved: last year only 3 systems could achieve this performance, with the majority of the systems having 5-10% less accuracy. **Modal pluperfect** is also ranging very low, scoring between 2.2% and 50.6% and similar is the case for its negated version. Other moods of the pluperfect make it particularly difficult for some systems, e.g. PROMT and Online-Z suffer in translating the **ditransitive** and **intransitive pluperfect**.

When trying to find the cases that consist a weakness for particular systems, Online-Z indicates one of the lowest scores in punctuation, which appears to derive from the fact that the system removes all **quotation marks**. A similar issue is observed with Online-G and OPPO which could correctly convey almost half of the quotation marks, whereas another two systems have some way to go. Interestingly enough, despite strongly depending on preprocessing, quotation marks are a common issue, since similar cases have been noted in previous years. In other phenomena, Online-Z has a very low accuracy for **sluicing** whereas PROMT is relatively weak concerning **lexical ambiguity**.

Table 3 contains further translation examples from linguistic phenomena with low accuracy. A *resultative predicate* is a construction that consists

Resultative Predicate	
Sie trinkt die Tasse leer.	
She drinks the cup empty.	fail
She empties the cup.	*pass*
She is drinking the whole cup.	*pass*
Intransitive Pluperfect	
Sie hatten geschlafen.	
They were sleeping.	fail
They had slept.	pass
Sluicing	
John mag die Nudeln nicht, aber er weiß nicht, warum.	
John doesn't like the noodles but he doesn't know why.	fail
John doesn't like the noodles, but he doesn't know why.	pass
Lexical Ambiguity	
Das Gericht gestern Abend war lecker.	
The court last night was delicious.	fail
The dish last night was delicious.	pass

Table 3: Examples of linguistic phenomena with low accuracy with passing and failing MT outputs

of a verb and an adjective in which the verb describes an action and the adjective describes the result of that action. In many cases, resultative predicates lead to translation errors as they do not exist in English and a literal translation leads to an ungrammatical translation, as can be seen in the example. Since none of the systems could produce a correct output for this sentence, we have provided two possible correct translations here as examples.

Intransitive verbs do not require further objects (as opposed to transitive or ditransitive verbs). *Pluperfect* is a tense which is used in German to describe completed actions that have taken place in the past. It should be translated to English in pluperfect as well. In the example, the incorrect translation contains past progressive *were sleeping* instead of the correct *had slept*.

Sluicing is a type of ellipsis that can occur in direct and indirect interrogative clauses. A wh-word precedes the part of the sentence that contains the ellipsis. In our example, all constituents following the wh-word are elided: *John mag die Nudeln nicht, aber er weiß nicht, warum ~~er die Nudeln nicht mag~~*. Sluicing exists in both German and in English: *John doesn't like the noodles, but he doesn't know why ~~he doesn't like the noodles~~*. One difference between the German and the English sluicing sentence is that in German there are two commas, while in English there is only one. Since this phenomenon concerns the complete sentence, punctuation should be correct when translating a sentence containing sluicing. In our example, the missing comma leads to fail.

The fourth example in the Table contains the lexical ambiguity *Gericht*. *Gericht* can either mean *court* or *dish* but the context provided in the sentence (*war lecker*, English: *was delicious*) serves as disambiguation so that only a translation referring to *dish* (or to food in some way) can be a pass. Any translation referring to *court/courthouse/tribunal* or the like is a fail.

WMT	categ. macro-	micro-
2018	81.0	**84.1**
2019	**87.4**	83.0
2020	**88.0**	**85.1**

Table 4: The accuracy (%) of the best system of each year as measured over 5,555 test items that were common over the last years. The scores that are significantly higher in each column are boldfaced

4.4 Comparison with previous years

One can notice some improvements on the overall performance of the best system, as compared with the previous two years. As seen in Table 4 from 2018 to 2019 there was a 6.4% improvement on the macro-averaged accuracy but there was no significant improvement from 2019 to 2020. The best system of 2019 was not submitted in 2020 and this is unfortunate, as it performed better than this year's best system in four categories (mostly regarding ambiguity; Table 6). When considering micro-averaged accuracy, there is significant improvement since last year (2.1%), but the best system of 2018 is competing with the one of this year, due to its high performance regarding verb tense/mood.

One can also consider the improvement of individual systems submitted to WMT from one year to another, starting from 2018. This year, only 5 of the 2019 systems submitted their new version and the yearly difference of their test suite accuracy can be seen in Table 6. The accuracy is measured over the test items that are common over all three years (or at least the last two).

All systems indicate considerable improvements on the macro-average since the previous year, ranging between 2,4% and 8,5%. Online-G had a major improvement for a second year in a row (21.6% in total), whereas it is the only system that achieved such an improvement without having an accuracy drop for any of the linguistic categories, whereas it improved 6 categories for more than 10%. PROMT

had improvement in all categories apart from verb tense/aspect/mood, UEdin deteriorated in verb tense/aspect/mood, whereas Online-B deteriorated in composition, named entity/terminology and punctuation.

The linguistic categories that improved mostly in average are the **long distance dependencies / interrogatives**, the **verb valency**, the **ambiguity** and the **punctuation**.

5 Conclusions and further work

In this paper we present the results of the application of the DFKI test suite in the output of the state-of-the-art MT systems participating in the Shared Task of the Fifth Conference of Machine Translation (WMT20). Based on about 5,500 test items, we present detailed accuracies regarding 107 phenomena organized in 14 categories. Additionally, the evolution of systems submitted also in previous years is observed.

The best system of this year is not significantly better than the one from 2019 in a macro-average, but one can see significant improvement from two years ago. The systems that seem to have the best accuracies are Tohoku and VolcanTrans. The phenomena that most systems face difficulties are again this year the idioms, the resultative predicates and some moods of the pluperfect, whereas some systems still have issues with quotation marks and lexical ambiguity.

As discussed previously, the high accuracies achieved for particular phenomena or categories raise questions on whether these phenomena are getting solved, or whether the test suite (which was originally built to challenge the systems from 2017) should raise the difficulty by including more test items.

In further work, we would like to be able to associate the performance on specific phenomena with decisions related to decisions during the development of the systems, once there is enough information about this process for all systems.

Abstract

Gender bias in machine translation can manifest when choosing gender inflections based on spurious gender correlations. For example, always translating doctors as men and nurses as women. This can be particularly harmful as models become more popular and deployed within commercial systems. Our work presents the largest evidence for the phenomenon in more than 19 systems submitted to the WMT over four diverse target languages: Czech, German, Polish, and Russian. To achieve this, we use WinoMT, a recent automatic test suite which examines gender coreference and bias when translating from English to languages with grammatical gender. We extend WinoMT to handle two new languages tested in WMT: Polish and Czech. We find that all systems consistently use spurious correlations in the data rather than meaningful contextual information.

1 Introduction

Bias in machine learning occurs when systems pick up correlations which are useful for specific training *datasets*, but are not indicative for the *task* that the dataset represents.

In the context of machine translation (MT), gender bias can occur when translating from languages without grammatical noun genders, such as English or Turkish, to a language with gender inflections, such as Spanish, Polish, or Czech. In such cases, the translation model needs to assign gender inflection in the target language based on contextual cues in the source text. For example, when translating the English sentence "The *doctor* asked the nurse to help *her* in the operation" to Spanish, the model needs to produce the female inflected "doctora" based on the feminine English pronoun "her".

Recently, Stanovsky et al. (2019) created a challenge set and an automatic evaluation metric, dubbed WinoMT, to examine whether popular MT models are capable of correctly capturing and translating such information from English into a diverse set of 8 target languages with grammatical gender. They found that all six tested systems, composed of four commercial and two academic models, consistently relied on gender role assignments in the data regardless of context. In our example above, models would prefer to translate the doctor using masculine inflections, despite the context suggesting otherwise.

In this work, we apply the WinoMT test suite on the submissions to the News shared task of WMT 2020. In addition to testing the phenomenon on a large number of models, we extend the WinoMT to the Polish and Czech languages, tackling unique language-specific challenges. We thoroughly analyze the extent of the phenomena for the tested languages and systems, as well as its correlation with the widely-used BLEU evaluation metric (Papineni et al., 2002), finding that systems with worse performance (in BLEU) make more errors for female professions than errors for male professions. On the other hand, better-performing systems (in BLEU) make more errors related to anti-stereotypical professions (e.g. female doctors, or male nurses).

Similarly to the conclusions of Stanovsky et al. (2019), we find that all systems consistently perform better when the source texts exhibit stereotypical gender role assignments (e.g., male doctors, female nurses) versus non-stereotypical assignments (e.g., female doctors, male nurses), indicating that these models rely on spurious correlations in their training data, rather than on more meaningful textual context. We hope that this evaluation will be used as a standard evaluation metric for MT as a means to track the improvement of this socially important aspect of translation.

Proceedings of the 5th Conference on Machine Translation (WMT), pages 357–364
Online, November 19–20, 2020.

2 Background: WinoMT

WinoMT was created as a concatenation of two coreference test suites: WinoGender (Zhao et al., 2018a) and WinoBias (Rudinger et al., 2018). Each instance in these datasets is a single English sentence, presenting two entities, identified by their profession (e.g., "teacher", "janitor", or "hairdresser") and a single pronoun referring to one of them based on the context of the sentence. For example, in the sentence "The physician hired the secretary because *he* was overwhelmed with clients", the marked pronoun refers to the physician. In contrast, in "The physician hired the secretary because *he* had good credentials" the pronoun likely refers to the secretary. Both datasets are created with an equal amount of stereotypical gender role assignments (e.g., the first example) and non-stereotypical assignments (e.g., the second example). Both works found that coreference systems performed much better on the stereotypical role assignments than they did on the non-stereotypical ones, concluding that systems relied on training correlations between pronoun gender and professions rather than the syntactic and semantic information in the input sentence.

Stanovsky et al. (2019) use these two corpora to test gender bias in machine translation in the following manner:

1. An MT model is used to translate these corpora into a target language with grammatical gender.

2. A language-specific, target-side morphological analysis identifies the gender of the translated entity (e.g., the physician in the first example above).

3. The gold and predicted genders are compared between the English and target sentence.

Following this procedure, they tested four commercial systems and two state-of-the-art academic models on eight diverse target languages: Spanish, French, Italian, Hebrew, Arabic, Ukrainian, Russian, and German. In all of their experiments, they found that similarly to coreference models, MT systems are prone to make gender-biased predictions.

In Section 3, we describe our extension of WinoMT to two additional languages tested in WMT 2020: Czech and Polish, and in Section 4 we use the extended test suite to evaluate WMT submission on a total of four target languages: Czech, German, Polish, and Russian.

3 New Target Languages: Polish and Czech

In this section, we describe our extension of WinoMT for Czech and Polish. The methods and analyses for both target languages are done by the first two authors, who are native speakers in the respective language.

For both languages, we followed the approach of WinoMT, where translated sentences are first aligned by fast_align (Dyer et al., 2013), followed by automatic morphology analysis.

Besides, we notice that the automatic alignment and existing tools sometimes fail leading to "unknown" gender decision. For both Czech and Polish, it could not recognise on average 10–15% test examples.

Fortunately, both languages have rich morphology where gender can be often identified from the word form. Therefore, we have created a list of the most often translations of each profession in all cases. Example of such a list is in Table 1. We use this list to the first check if the gender can be recognised solely based on the word form. In case that the word is not in our predefined list or if both the male and female version are possible. We revert to language-specific automatic analysis, as described below.

This step significantly reduced the number of unrecognised genders. In Section 3.4, we discuss the number of unrecognised genders of the profession.

3.1 Czech analysis

For translated professions in Czech that were not resolved by the predefined list, we use the automatic morphology tagger MorphoDiTa (Straková et al., 2014). This tool uses a morphological dictionary and estimates regular patterns based on common form endings, by which it clusters morphological "templates" without linguistic knowledge of Czech.

When analysing Czech, we ignore all examples that test neutral form, as Czech does not use neutral case as a grammatical structure allowing both genders.[1] Additionally, we ignore a few idiosyncratic edge cases: The word "advisee" cannot be directly

[1] In a few cases, the neutral form can be created by inaccurate translation, when replacing a profession with a place, where the professional works. For example, "hairdresser" can be replaced by "hair saloon" which is neutral in Czech.

Profession	Gender	Possible forms
Chef	Male	šéfce, šéfka, šéfko, šéfkou, šéfku, šéfky, náčelnice, náčelnici, náčelnicí, ...
Chef	Female	šéf, šéfa, šéfe, šéfem, šéfovi, šéfu, náčelník, náčelníka, náčelníkem, ...
Cashier	Male	pokladní, pokladního, pokladním, pokladnímu
Cashier	Female	pokladní

Table 1: Example of a list of possible forms for a given profession and gender (some forms are missing). Some professions have several possible translations; in this example "chef" has two possible translations. In Czech, most of the forms are distinct between male and female form. However, it is not always the case as can be seen for example for "cashier", where both male and female can have the form "pokladní". In those cases, we need to rely on automatic annotation based on the context of the whole sentence.

translated into Czech, while "guest" and "mover" do not have a female counterpart.

Altogether, we exclude 470 examples from WinoMT, reducing its size for Czech analysis to 3418 examples.

Lastly, certain translated professions have the same form for both male and female, for example, the word "vedoucí" ("supervisor", either male or female). In such cases, our analysis cannot correctly assign correct gender. Therefore we mark these example as a correct with the use of the gold data.

3.2 Polish analysis

For translated professions in Polish that are not found in the prepared list of possible word forms, we conduct an automatic morphological tagging to find their grammatical gender. For that purpose, we use a recently released spaCy model (Honnibal and Montani, 2017) with tagger for Polish (Tuora and Kobyliński, 2019), which relies on dictionary-based morphology analysis performed by Morfeusz (Woliński, 2014).

Similarly to Czech, in Polish, there are no names of professions with a neutral gender. Therefore for Polish analysis, we also ignore test cases for neural form. Additionally, we do not evaluate gender for the professions that do not have a polish translation, i.e. "advisee" and "mover". This reduces the Polish testset to 3136 examples.

In Polish, it is possible to indicate gender for almost all profession names. In most cases, it can be formed by changing the suffix of the word. Nevertheless, for specific occupations, female counterparts created by derivation are rarely used and do not appear in major language dictionaries. For such professions, a feminine variant is obtained by adding a word indicating gender in front – usually "pani(ą)" ("mrs.") before the masculine form of the occupation name. In our evaluation, we accept both variants.

We have identified 16 professions without feminine derivations in the on-line version of the Grammatical Dictionary of Polish (Woliński and Kieraś, 2016). These words are: "appraiser", "driver", "electrician", "engineer", "firefighter", "investigator", "mechanic", "pathologist", "plumber", "scientist", "sheriff", "surgeon", "taxpayer", "veterinarian", "witness", and "guest". We decided to keep these test cases because we observed a few interesting examples of correctly translating gender for them (as discussed in section 4.3) and see a potential for further improvement.

3.3 Human Annotation

We conducted a human evaluation of gender bias for the two new languages. We sampled 300 instances from the output of all systems; each sample was annotated by two Czech and two Polish native-speakers, with a third annotator resolving differences. Following the human evaluation protocol of Stanovsky et al. (2019), annotators were shown an entity in English and the translated sentence. They were asked to provide the gender of the entity in the target language.

We then compared human annotations with the output of our morphological analysers in both languages. The inter-annotator agreement was high: 96.3% for Czech and 98.6% for Polish. Finally, the performance of both system was good enough to support further analyses — the Czech analyser achieved 96.3% accuracy, while the Polish analyser achieved 98.8%. Both of these numbers surpass the average performance reported in (Stanovsky et al., 2019) of 87%.

Furthermore, our whitelisting approach for Czech can resolve almost all cases. From our WMT20 testsuite evaluation, it resolved all but

284 sentences out of 46,656 evaluated by all systems. We conducted a human annotation over these 284 sentences and found out that our automatic approach can correctly resolve 64.3 % examples. Likewise for Polish, whitelist approach failed in only 1,533 out of 47,267 examples, where it needed to rely on the morphology evaluation. We selected 300 random sentences from this subset for human evaluation. The agreement between our morphology algorithm and annotators was 78.7%. We have to stress that those are the most challenging examples and most often incorrect translations.

3.4 Unrecognized Gender

When neither whitelisting nor contextual morphological analysis recognise gender properly, our automatic assigns an "unknown" gender. This happens mostly for erroneous translations, when the translation does not contain the profession at all (for example when "hairdresser" is translated as a "hair salon"), or when an error is made by the alignment or morphology annotation.

We consider two approaches for handling such unrecognised genders. We could ignore examples with "unknown" gender, or we can count them as errors. The former approach would change the ratio between male and female professions differently for each system; in other words, each system would have a testset of different size based on its performance. The latter approach, on the other hand, will punish systems for an error is in the analysis. We follow WinoMT, where the latter approach is selected.

To estimate the implication of this choice, in Table 2 we present the average percentage of "unknown" genders when a gold label is male or female. The percentage is averaged across all systems. We can notice that number of unknowns is a minimal form all languages except Russian, and the difference between unrecognised male and female professions is small. Therefore, it should not skew the results of the analysis.

We observe that the errors are usually due to the translation issue. For example, in Czech, the system with the most unrecognised genders is also the worst-performing in terms of BLEU. This system ("zlabs-nlp") has 248 unrecognised professions out of the whole testset, while the average for all systems is 90, and it has a performance of 20.3 BLEU score, while the second-worst system has a performance of 25.3 BLEU.

Target Language	Unknown Male	Unknown Female
Czech	1.33%	1.30%
German	1.61%	1.38%
Polish	1.37%	1.84%
Russian	12.89%	13.53%

Table 2: The percentage of "unknowns" for gold male or female labels, averaged across all submissions for a target language.

The Russian analysis cannot recognise more than 12% of professions. We believe that this could be improved in the future with the whitelisting approach as was done for Czech and Polish.

4 Evaluation

We continue with the analysis as described by Stanovsky et al. (2019). For each system, we compute three metrics that represent their ability to resolve gender coreference; or how often the systems resolve the gender-based on stereotypical genders of professions. All results are in Table 3.

4.1 Results

Overall accuracy. First, the overall system Accuracy (abbreviated as "Acc") is calculated as a percentage of instances in which the translation preserved the gender of the profession from the original English sentence. We find that most systems perform better than random guessing. One exception is the Russian language, where all systems perform worse than random guessing. This could be related to a problematic analysis as mentioned in Section 3.4, where all systems are penalised for "unknown" genders, which results in lowering their accuracy. Overall, the system with the best accuracy is CUNI-DocTransformer on the Czech language. This system has been trained on a document-level instead of separate sentences, which may have helped it learn to resolve coreference better than sentence-level systems. Among systems that participated in all four languages, *OPPO* performs the best, also outperforming commercial systems (anonymised as "online-X").

Gender-based performance analysis. Second, we compute the difference Δ_G in performance (F1 score) between male and female translated professions. Δ_G=0 means that the system makes an equal number of errors on both male and female professions. This should be the correct case in ideal conditions as there is an equal number of male and

Table 3: The evaluation on WinoMT testset for translation systems submitted to WMT 2020. *Acc* indicates overall gender accuracy (% of instances the translation had the correct gender), Δ_G denotes the difference in performance (F1 score) between masculine and feminine scores, and Δ_S is the difference in accuracies between pro-stereotypical and anti-stereotypical gender role assignments.

female examples in WinoMT. Positive Δ_G indicates that the system makes fewer errors for male professions and more errors with female professions. Almost all systems perform significantly better on male professions. This could be a result of training data that contains more male examples than female ones. However, we observe that many systems have Δ_G close to zero. An interesting situation is in Czech analysis, where there is a broad range of Δ_G values.

Stereotypical vs non-stereotypical examples Third, we measure the difference Δ_S in performance (F1 score) between stereotypical and non-stereotypical gender role assignments. The stereotypicality of the profession was determined based statistics provided by the US Department of Labor (see Zhao et al. (2018b)). Δ_S in Table 3 shows that all systems have a significantly better performance when presented with pro-stereotypical assignments (e.g., a female nurse), while their performance deteriorates when translating anti-stereotypical roles (e.g., a male receptionist). These analyses indicate that all MT systems are gender-biased, prone to translate gender inflexions based on training set correlations rather than contextual cues in specific input instances.

4.2 Gender Bias vs BLEU

Another interesting comparison is between the overall translation performance of a system and its observed gender bias. Unfortunately, the official WMT human annotation was not available to us at the time of writing. Instead, we evaluate the performance of all systems with the automatic BLEU metric (Papineni et al., 2002). The evaluation is done with official WMT20 testset (Barrault et al., 2020) and the SacreBLEU implementation (Post, 2018).[2]

In Fig. 1 we present pairwise relationships and correlations between our metrics (Accuracy, Δ_G, Δ_S) and BLEU. We observe that correlation between gender accuracy and BLEU is moderately strong (Pearson's ρ 0.66). There is a significant negative association between Δ_G and both gender accuracy and BLEU, meaning that systems scoring high in those metrics perform similarly well on male and female examples. We observe a low positive correlation between BLEU and Δ_S and a moderate positive correlation between gender

[2]SacreBLEU signature is: BLEU+case.mixed+numrefs.1 +smooth.exp+tok.13a+version.1.4.14

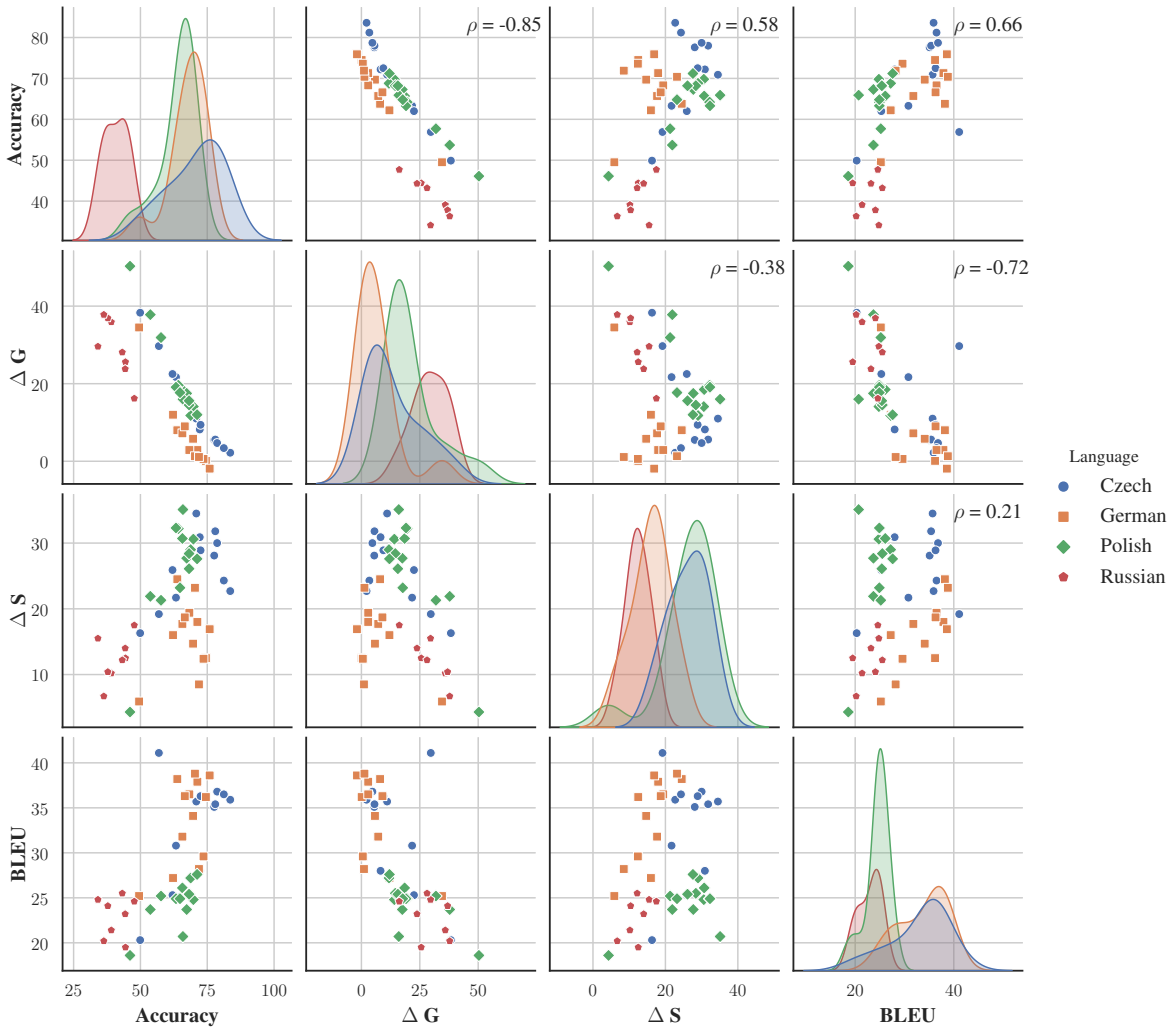

Figure 1: Relationships between gender accuracy, ΔG, ΔS and BLEU. Each point represents evaluation of one system's output. ρ in the upper right is Pearson's correlation coefficient between row and column variables.

accuracy and Δ_S. It implies that the system well-performing in the automatic evaluation may overfit to examples with stereotypical gender.

4.3 Qualitative Analysis

In our analysis of new target languages: Czech and Polish, we have observed several linguistic phenomena that affect gender bias of translations. We illustrate them with exemplary translations of WinoMT test sentences in Table 4.

In Polish, feminine forms of some words are not commonly used, e.g., "mechanic" and "veterinarian". We provide a complete list of occupations is in Section 3.2. According to our expectations, such words are especially problematic for evaluated systems. The female gender was correctly assigned in only 1.5% of the translations. Interestingly, in some cases, a word indicating female gender is added, even though it is not used in a source sentence (see in Table 4), such a translation is marked as correct.

5 Conclusions

We have extended analysis by Stanovsky et al. (2019) with Czech and Polish languages.

We showed that current systems, both commercial and academic, perform worse in gender coreference when profession in question is female. This is amplified if the system in question has lower translation quality.

Moreover, systems rely for translations on stereotypical genders of professions instead of correct gender coreference resolution. We showed that with increasing translation quality, models make fewer errors in general, but rely more often on the stereotypical genders.

Source	[Target lang.] Translation	Phenomenon
The librarian waved at the **mechanic** and walked away from **her**.	[PL] Bibliotekarka pomachała do **mechanika** i od **niej** odeszła.	Female form for "mechanic" in Polish is rarely used, hence it did not occur in output of the evaluated translation systems.
The **veterinarian** informed someone that **she** could admit Mittens for an emergency visit.	[PL] **Pani weterynarz** poinformowała właściciela, że może przyjąć Mitens na nagłą wizytę.	Word "weternenarz" has a masculine gender, but translation correctly captures gender by adding word "pani" ("mrs.").
The **chief** thanked the **nurse** and handed **him** a present.	[CS] **Sestřička** poděkovala **primáři** a dala **jí** dárek.	There is a missmatch in translation, as female form "jí" refers to male "primáři". Moreover, it swapped actors in the translation.
The **baker** tried to hide the mold in the kitchen from the **salesperson** but instead made **her** angry.	[CS] **Prodavač** si všiml **pekařovy** nechutné kuchyně a řekl **mu**, aby přestal prodávat chleba.	In this translation, the profession is in adjective, which we are unable to detect by our analysis.

Table 4: Examples of interesting linguistic phenomena observed for translation of WinoMT sentences into new target languages. Words in **blue**, **red**, and **orange** indicate male, female and neutral entities, respectively.

This is mainly a problem with the MT training data, that usually contain more examples of stereotypical professions in contrast to anti-stereotypical ones.

Acknowledgments

This study was supported in parts by the grants 18-24210S of the Czech Science Foundation and 825303 (Bergamot) of the European Union. This work has been using language resources and tools stored and distributed by the LINDAT/CLARIN project of the Ministry of Education, Youth and Sports of the Czech Republic (LM2015071).

We also also would like to thank Joanna Wetesko and Maciej Biesek for discussions about the role of grammatical gender in Polish and their help with the evaluation.

The MuCoW word sense disambiguation test suite at WMT 2020

Yves Scherrer **Alessandro Raganato** **Jörg Tiedemann**
University of Helsinki
{name.surname}@helsinki.fi

Abstract

This paper reports on our participation with the MuCoW test suite at the WMT 2020 news translation task. We introduced MuCoW at WMT 2019 to measure the ability of MT systems to perform word sense disambiguation (WSD), i.e., to translate an ambiguous word with its correct sense. MuCoW is created automatically using existing resources, and the evaluation process is also entirely automated. We evaluate all participating systems of the language pairs English → Czech, English ↔ German, and English → Russian and compare the results with those obtained at WMT 2019. While current NMT systems are fairly good at handling ambiguous source words, we could not identify any substantial progress – at least to the extent that it is measurable by the MuCoW method – in that area over the last year.

1 Introduction

At WMT 2019, we introduced the MuCoW (*multilingual contrastive word sense disambiguation*) test suite (Raganato et al., 2019) and evaluated the news task submissions of nine translation directions with it.[1] We observed that systems generally performed quite well on word sense disambiguation, but found a big gap between in-domain and out-of-domain disambiguation performance for some translation directions, in particular with constrained systems.

For WMT 2020, we reuse the same test suite for the same language pairs. This gives us the opportunity to measure the advancement of machine translation within a year. We expect the larger training data sets and the model improvements to have a small but positive impact on translation quality in general, and word sense disambiguation performance in particular.

[1]The MuCoW test suite is available at http://github.com/Helsinki-NLP/MuCoW.

2 The MuCoW test suite

MuCoW (Raganato et al., 2019) is a language-independent method for automatically building test suites to assess the capabilities of MT systems to disambiguate between ambiguous words in the source language. The version of MuCoW used for WMT 2019 involves the following steps:

1. Identify ambiguous source nouns and their translations, using word-aligned and tagged parallel corpora from the OPUS collection (Tiedemann, 2012).

2. Cluster the translations into senses. First, we query BabelNet (Navigli and Ponzetto, 2012), a wide-coverage multilingual encyclopedic dictionary, to assign senses (synsets) to words. Second, we refine the results with the SW2V sense embeddings (Mancini et al., 2017).

3. Select sentences with ambiguous words and assign them sets of correct and incorrect target translations.

We evaluated the systems participating in the WMT 2019 news translation task with MuCoW for the language pairs English → Czech, English ↔ German, English ↔ Finnish, English ↔ Russian, and English ↔ Lithuanian.

A substantial amount of MuCoW sentences and senses come from the OpenSubtitles2018 corpus, but most systems participating at WMT are tuned towards the news domain and therefore are not expected to handle lexical choices of colloquial speech reliably. Therefore, we distinguished between in-domain and out-of-domain synsets: a synset is considered out-of-domain if more than half of its example sentences come from movie subtitles.

Proceedings of the 5th Conference on Machine Translation (WMT), pages 365–370
Online, November 19–20, 2020.

Example containing **ambiguous word**	Correct translations	Incorrect translations
It occurred to me that my **watch** might be broken.	Armbanduhr, Uhr	*Wache*
I hope you didn't get distracted during your **watch**.	*Wache*	Armbanduhr, Uhr
In winter, the dry leaves fly around in the **air**.	Luft, Luftraum, Aura	Miene, Ausdruck
He remained silent for a moment, with a thoughtful but contented **air**.	Miene, Ausdruck	Luft, Luftraum, Aura
Harry had to back out of the competition because of a broken **arm**.	Arm	*Waffe*
So does the cop who left his side **arm** in a subway bathroom.	*Waffe*	Arm
Drain the pasta and return the pasta to the **pot**.	Blumentopf, Kochtopf, Topf, Nachttopf	*Marihuana, Gras*
Where did those idiots get all of this **pot** anyhow?	*Marihuana, Gras*	Blumentopf, Kochtopf, Topf, Nachttopf

Table 1: Examples of test suite instances of the English–German test suite. The ambiguous (English) source word is highlighted in bold, and correct and incorrect (German) translations – as inferred by the MuCoW procedure – are given. Senses classified as out-of-domain are shown in italics. Note that some example sentences may further restrict the set of correct translations.

Language pair	Source words	Target synsets	In-dom synsets	Out-dom synsets	Sentences
EN–CS	98	200	29	171	1843
EN–DE	176	362	220	142	3337
DE–EN	217	461	329	132	4268
EN–RU	97	199	40	163	1814

Table 2: Sizes of the MuCoW data sets compiled for WMT 2019 and 2020.

In Raganato et al. (2020), we report on an extended version of MuCoW that covers the following aspects:

- The selection of data sources is improved to reduce noise and domain effects.
- The sense inference process is streamlined and relies on lemmatization instead of word alignment, leading to better coverage especially for morphologically rich languages.
- In addition to test sets, the composition of training data is also defined to guarantee that competing translation models are evaluated on fair grounds.

Since it was not possible to restrict the training data of participating WMT systems, we decided to reuse the WMT 2019 version again for WMT 2020, with exactly the same sentences. This allows us to trace the year-over-year evolution of translation quality with respect to lexical disambiguation. Therefore, the MuCoW analysis is restricted to the language pairs and translation directions that were already part of the WMT news task in 2019, namely English → Czech, English ↔ German, and English → Russian.

MuCoW data sets are created specifically for each language pair and translation direction (for details, see Raganato et al., 2019). Each entry consists of a sentence in the source language, the ambiguous source word, a list of correct target words (the correct target synset), a list of incorrect target words (the incorrect target synset), and information about the domain of the synsets. The participants only see the source sentences, not the metadata. Table 1 shows a few example sentences taken from the English–German test suite. The main statistics of the test suites used for WMT 2020 are reported in Table 2.

3 Evaluation and Results

The source language sentences were sent to the WMT participants as part of the test set, and we received the translations in the target language for evaluation. We then checked if any of the correct or incorrect target words listed in the metadata file could be identified in the translation output.

Although the sentences were selected to contain the uninflected base forms both in the source and target languages, we could not assume that all translation systems would output base forms. Hence, if neither correct nor incorrect target words could be identified in the tokenized translations, we lemmatized them and searched the target words again in the lemmatized version.[2] Depending on the morphological properties of the target language, lemmatization substantially increased the coverage (see Table 3). Between 2019 and 2020, the average coverage has remained constant

[2]We used the Turku neural lemmatizer with pretrained models (Kanerva et al., 2019).

Language pair	Avg. coverage (tokenized)	Avg. coverage (tok. + lemmatized)
EN–CS	63.16%	75.82%
	61.77%	*74.87%*
EN–DE	69.43%	72.08%
	66.52%	*69.26%*
DE–EN	83.10%	84.41%
	83.06%	*84.51%*
EN–RU	65.13%	80.13%
	58.88%	*73.29%*

Table 3: Average coverage of target words among WMT 2019 (in gray italics) and WMT 2020 (in black) primary submissions.

for DE–EN, slightly increased for EN–CS and EN–DE, and substantially increased for EN–RU. We assume that these increases are mostly due to the different number and composition of the submissions.

We report precision, recall and F1-score for in-domain senses and out-of-domain senses separately. Precision and recall are computed as follows:[3]

$$\text{Precision} = \frac{\text{\# examples with correct target words}}{\text{\# examples with either correct or incorrect target words}}$$

$$\text{Recall} = \frac{\text{\# examples with correct target words}}{\text{\# total examples}}$$

The results are shown in Tables 4 to 7, with WMT 2019 and 2020 submissions side-by-side.

For all four examined translation directions, the best 2019 results were beaten in 2020. However, one of the best-performing systems in 2019, *Facebook_FAIR*, did not participate in 2020. The *Facebook_FAIR* system is characterized by high precision rates, whereas the winning 2020 systems (such as *Tohoku-AIP-NTT* or *Online-G*) benefit from higher recall. This shift suggests that the denominator of the precision computation comes closer to the one of the recall computation, or in other words that the translations themselves become more accurate. Further analysis will be required to substantiate this claim.

Interesting year-over-year comparisons can be observed for the *Online-G* system: it produces almost identical results in both years for English–German and English–Russian, but shows substantial improvements for the German–English direction.

[3]Examples that contained both correct and incorrect target words were counted as incorrect.

The overall result distributions show a slight upward trend in WSD performance for English–German and German–English, but less so for English–Czech and English–Russian. Since the participating systems differed over the years, it is of course difficult to draw any reliable conclusions.

For most language pairs, the in-domain and out-of-domain synsets produce similar rankings. Just like in 2019, English–Czech is an exception, where – contrarily to all expectations – an online system shows the best in-domain performance and a research system the best out-of-domain performance.

4 Conclusion

In this paper, we report our participation with the MuCoW test suite at the WMT 2020 news translation task. MuCoW is an automatically built WSD test suite for machine translation that relies on large parallel corpora, the multilingual lexical resource BabelNet and language-independent synset embeddings.

We find that state-of-the-art NMT systems are fairly good at handling ambiguous source words, but that no substantial progress – at least to the extent that it is measurable by the MuCoW method – has been made in that area over the last year. Among the top-performing systems, we observe a shift from high precision to high recall, hinting at general improvements in translation quality. It will therefore be particularly instructive to see how well the WSD test suite results correlate with human evaluation scores and with recently proposed evaluation metrics that are based on semantic representations of the translations (Gupta et al., 2015; Shimanaka et al., 2018).

Abstract

Even though sentence-centric metrics are used widely in machine translation evaluation, document-level performance is at least equally important for professional usage. In this paper, we bring attention to detailed document-level evaluation focused on markables (expressions bearing most of the document meaning) and the negative impact of various markable error phenomena on the translation.

For an annotation experiment of two phases, we chose Czech and English documents translated by systems submitted to WMT20 News Translation Task. These documents are from the News, Audit and Lease domains. We show that the quality and also the kind of errors varies significantly among the domains. This systematic variance is in contrast to the automatic evaluation results.

We inspect which specific markables are problematic for MT systems and conclude with an analysis of the effect of markable error types on the MT performance measured by humans and automatic evaluation tools.

1 Introduction

This paper presents the results of our test suite for WMT20 News Translation Task.[1]

The conclusion of Vojtěchová et al. (2019), a last year's similar effort, states that expert knowledge is vital for correct and comprehensible translation of professional domains, such as Audits or Lease agreements. Furthermore, even MT systems which make fewer mistakes and score above others in both automatic and manual evaluations are prone to making fatal errors related to markable conflicts, which render the whole document translation unusable.

In this study, we aim to organize and describe a more detailed study with a higher number of annotators. We show three evaluation approaches: (1) automatic evaluation, (2) fluency and adequacy per document line and (3) detailed markable phenomena evaluation. We compare the results of this evaluation across the three domains and try to explain why all of these evaluations do not produce the same ordering of MT systems by performance.

This paper is organized accordingly: Section 1.1 defines the term "Markable", Section 1.2 describes the examined documents and Section 2 introduces the two phases of our annotation experiment and shows the annotator user interface in Section 2.3. In Section 3, we discuss the results from both phases and also automatic evaluation. The main results of this examination are shown in Section 3.5 and specific markable examples are discussed in Section 4. We conclude in Section 5.

1.1 Markable Definition

A markable in this context is an occurrence of any technical or non-technical term or expression that satisfies at least one of the following conditions:

1. The term was translated into two or more different ways *within one document*.
2. The term was translated into two or more different ways *across several translations*.
3. Two or more terms were translated to a specific expression *in one document* but have different meanings.

To be a markable, the term or expression does not have to be a named entity, but it must be vital to the understanding of the document. In the same order we show examples which satisfy the definition conditions.

1. *bytem* – It was translated within one document into *an apartment* and *a residence*.

Online, November 19–20, 2020.

Document	Sentences	Direction	Markable occurrences	Description
Lease	29	cs→en en→cs	73 70	Housing lease agreement
Cars	18	cs→en	11	Brno Grand Prix competition article + highway accident report
Audit	90	cs→en en→cs	28 18	Supreme Audit Office audit report
Speech	13	en→cs	15	Greta Thunberg's U.N. speech article
Total	**269**	-	**215**	-

Table 1: Summary of examined documents with translation directions, number of lines and number of markable occurrences.

2. *rodné čísla* – It was translated in one translation to *social security number* and in another translation to *identification number*.
3. *nájemce*, *podnájemce* – They have different meanings and in one document they were both translated to tenant.

Markables were proposed first by the annotators in the first phase of annotation in Section 2.1 and then filtered manually by us.

1.2 Test Suite Composition

We selected 4 documents, 2 of which were translated in both directions totalling 6 documents. We chose 2 from the professional domain (Audit and Lease) and 2 from the News domain. The overview of their size is shown in Table 1. The number of markable occurrences is highly dependent on the document domain with the Agreement domain (Lease document) containing the most occurrences.

All of the MT systems are participants of the News Translation Task, and we test their performance even outside of this domain. Most of them were bi-directional, and we join the results from both directions when reporting their performance. The only exceptions are eTranslation (only en→cs) and PROMT_NMT (only cs→en).

1.3 Data and Tools Availability

All of the document translations and measured data are available in the project repository. Furthermore, the used online markable annotation tool written in TypeScript and Python is documented and also open-source.[2]

[2] github.com/ELITR/wmt20-elitr-testsuite

2 Annotation Setup

For both phases of this experiment, we used 10 native Czech annotators with English proficiency. None of them were professional audit or legal translators. Because each annotator annotated only one or two documents, the aggregated results across domains, labelled as *Total*, are of less significance than the results in individual domains.

2.1 Manual Document Evaluation

In this phase of the experiment, we wanted to measure the overall document translation quality and also to collect additional markables for use in the following experiment part. We showed the annotators the source document (in Czech) with a line highlighted and then underneath all its translation variants (in English). The current line was also highlighted. Next to every translation was a set of questions related to the just highlighted lines:

- **Adequacy**: range from 0 (worst) to 1 (best) measuring how much the translated message is content-wise correct regardless of grammatical and fluency errors.
- **Fluency**: range from 0 (worst) to 1 (best) measuring the fluency of the translation, regardless of the relation of the message to the source and the correct meaning.
- **Markables**: A text area for reporting markables for the second phase.
- **Conflicting markables**: checkbox for when there is a markable in conflict (e.g. the terminology change) with a previous occurrence in the document. This corresponds to the first condition in the markable definition in Section 1.1. The default value was *No* (no

conflict) because the distribution was highly imbalanced.

Bojar et al. (2016) summarize several methods for machine translation human evaluation: Fluency-Adequacy, Sentence Ranking, Sentence Comprehension, Direct Assessment, Constituent Rating and Constituent Judgement. For our purposes, we chose a method similar to Fluency-Adequacy as one of the standard sentence-centric methods. The difference to the method described is that we showed all the competing MT systems at once, together with the whole document context. Ultimately, we would like the users to rate Fluency-Adequacy of the whole documents, but we suspected that asking annotators to read the whole document and then rating it on two scales would yield unuseful biased results.

2.2 Manual Markable Evaluation

In the following phase, we focused on markables specifically. For every markable in the source, we asked the annotators to examine 11 phenomena. If the given phenomenon is present in the examined markable occurrence, a checkbox next to it should have been checked (Occurrence). Further on a scale 0–1 (not at all–most) the annotator should mark how negatively it affects the quality of the translation (Severity). We list the 11 phenomena we asked the annotators to work with:

- **Non-translated**: The markable or part of it was not translated.
- **Over-translated**: The markable was translated, but should not have been.
- **Terminology**: The translation terminology choice is terminologically misleading or erroneous.
- **Style**: An inappropriate translation style has been selected, such as too formal, colloquial, general.
- **Sense**: The meaning of the whole markable translation is different from what was intended by the source.
- **Typography**: Typographical errors in translation such as in capitalization, punctuation, special character or other typos.
- **Semantic role**: The markable has a different semantic role in translation than in the source. Without any specific linguistic theory in mind, we provided four basic roles for illustration: agent (story executor), patient (affected by the event), the addressee (recipient of the object in the event), effect (a consequence of the event).
- **Other grammar**: Other grammatical errors such as bad declension or ungrammatical form choice.
- **Inconsistency**: A different lexical translation option than the previous occurrence was used. It is enough to compare only with the previous occurrence and not with all of them.
- **Conflict**: The translation conflicts with another markable or term in the document. This and another markable translates to the same word.
- **Disappearance**: The markable does not appear in translation at all.

The choice to focus on markables was motivated by the aim to find a way to measure document-level performance using human annotators. A good markable translation is not a sufficient condition for document-level performance, but a necessary one. This approach is similar to Constituent Ranking/Judgement described by Bojar et al. (2016) with the difference that we chose to show all the markable occurrences in succession and in all translations in the same screen. We showed the whole translated documents context so that the annotators could refer to previous translations of the markable and the overall context.

2.3 Interface

Figure 1 shows the online interface for the second phase of this experiment. The first text area window contains the source document (e.g. in English). Below it are several translations (e.g. in Czech). Next to each translation is a set of questions. In the source, the current markable occurrence, to which the questions relate, is always displayed in dark blue. The current sentence is highlighted in the translations with light blue. The target words which probably correspond to the current markable (via automatic word alignment) are highlighted in dark blue as well. This alignment is present only for quick navigation as it is not very accurate. In translations, the remaining occurrences of a given markable are highlighted in green to simplify checking for inconsistency.

The FOCUS button is used to scroll to the current line in all text areas in case the user scrolled the view to examine the rest of the document.

In the first phase, the annotators could return to their previous answers and adjust them, but before

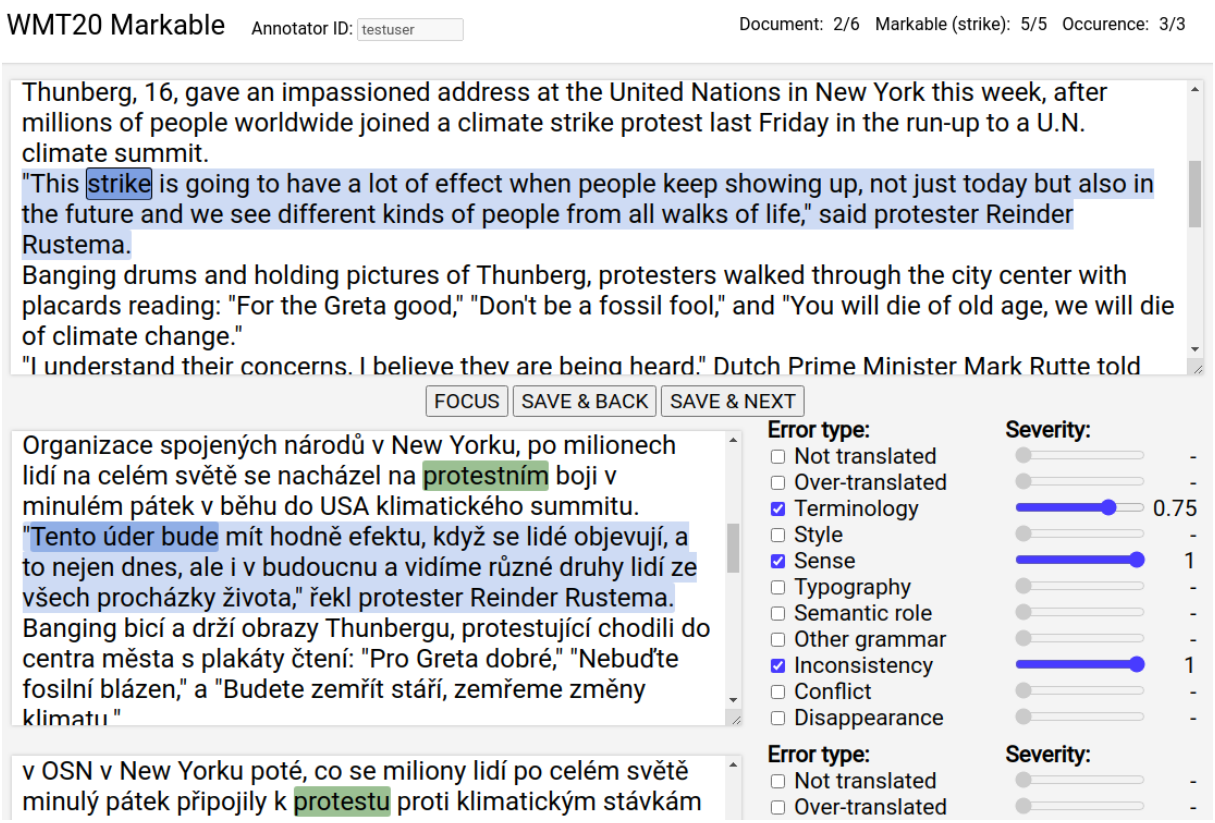

Figure 1: Online interface for markable annotation with highlighted segments. The 12 other translations are in the rest of the page, not fully visible here.

continuing to the next line, they had to fill in the current fluency and adequacy. In the second phase, the annotators could freely return to their previous answers and adjust them. The most straightforward approach for them was to annotate a single markable occurrence across all MT systems and the switch to the next one as opposed to annotating all markable occurrences in the first translation, then all markable occurrences in the second translation, and similarly the rest.

As soon as we aggregate the statistics over multiple documents (or even translation directions), the effects of which particular annotator annotated which document can start playing a role, but we hope they cancel out on average.

3 Results

3.1 Automatic Evaluation

We measured the system quality using BLEU (Papineni et al., 2002) against a single reference. The results sorted by the score across all documents are shown in Table 2. BLEU scores across different test sets are, of course, not comparable directly. Only a very big difference, such as that of eTranslation for News and Audit (39.43% and 23.23%) suggests some statistically sound phenomena. We measured the standard deviation across MT systems within individual domains: News (6.19), Audit (2.34) and News-Lease (2.74). The Audit domain was generally the least successful for most of the submitted systems (see Table 3) and the Lease domain was more stable in terms of variance. The MT system BLEU variance over annotated lines hints that the better the system, the higher variance it has. This may be because most of the best MT systems are focused on News and fail on other domains, while the lower performant MT systems are low performant systematically across all domains.

3.2 Overall Manual Evaluation

From the first phase (Section 2.1) we collected $13 \times 328 = 4264$ line annotations. From the second phase (Section 2.2) we collected $13 \times 499 = 6487$ markable annotations. The average duration for one annotation of one translated line in the first phase was 25s, while one annotation of one system-markable occurrence in the second phase took only 8s.

Fluency and Adequacy correlate per line together

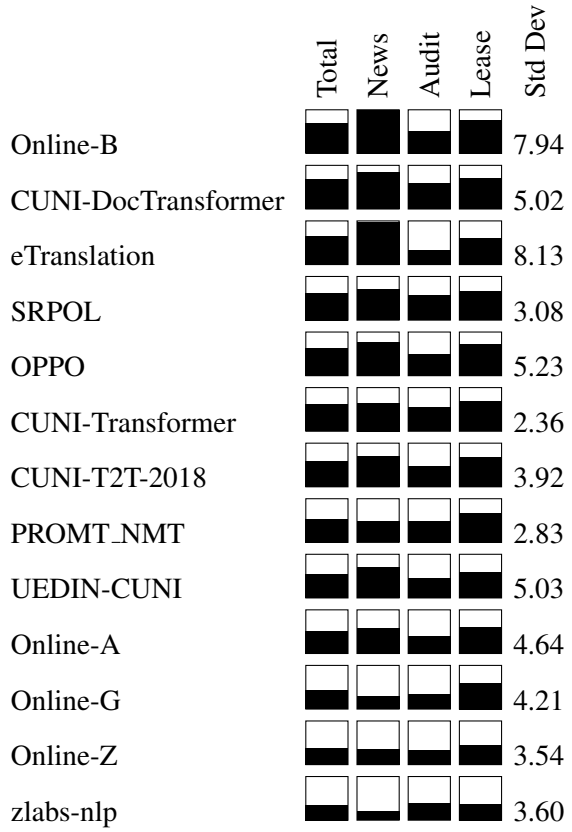

Table 2: MT system results measured by BLEU together with standard deviation measured from all sentences. Sorted by the first column. Full black box indicates 40% BLEU, empty 15% BLEU.

strongly (0.80), and their product correlates negatively (-0.33) with the number of wrong markables. Because of this strong correlation and also the need to describe the result of the first phase by one number, we focus on Fluency×Adequacy. Table 3 shows the average Fluency×Adequacy as well as the average number of reported wrong markables per line.

Document	Mult.	Mkbs.	BLEU
Audit →cs	0.95	0.08	28.61 ±5.13
Audit →en	0.81	1.23	32.68 ±5.07
Lease →cs	0.78	0.33	33.50 ±4.96
Lease →en	0.78	0.30	35.44 ±4.94
News →en	0.74	0.65	30.68 ±5.05
News →cs	0.65	0.83	38.67 ±4.93
Average	0.79	0.73	33.57 ±4.93

Table 3: Document average (across all systems) of Fluency×Adequacy (Mult.), number of reported wrong markables per line (Mkbs.) and BLEU.

3.3 MT System Performance

The performance per MT system and domain can be seen in Table 4. The reference translation received a comparably low rating in especially the Audit domain and fared best in the News domain. We see this as a confirmation of the last year's observation and a consequence of using non-expert annotators, who may have not annotated more complex cases thoroughly and were more content with rather general terms and language than what is correct for the specialized auditing domain.

No system has shown to be risky (high average but also with high variance). The last column in Table 4 shows, that the better the system, the more consistent it is (lower variation across documents). This did not occur with BLEU.

The ordering of systems by annotator assessment is slightly different than by automatic evaluation (Section 3.1). The automatic evaluation correlates with annotator rating (Fluency×Adequacy) with the coefficient of 0.93 (excluding Reference).

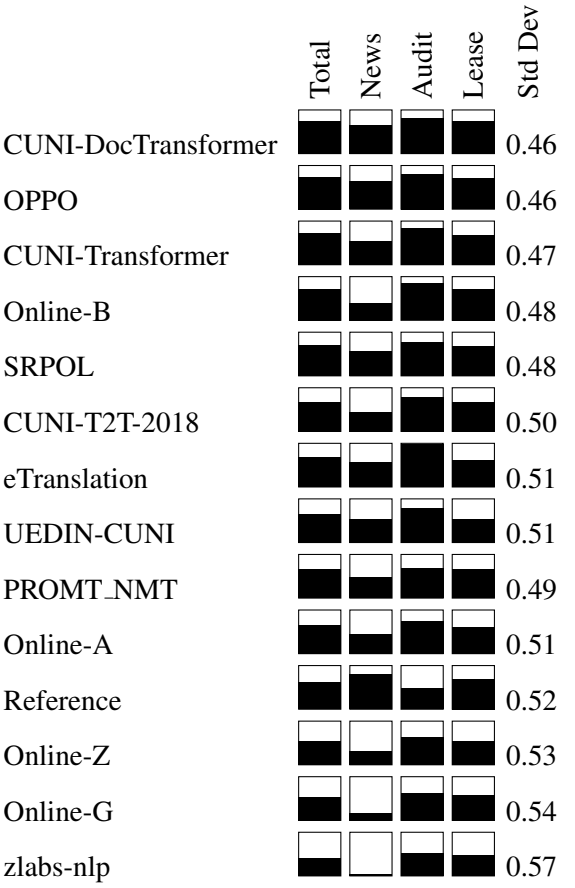

Table 4: MT system results measured by Fluency×Adequacy together with standard deviation measured from Total. Sorted by the first column. Full black box indicates 100%, empty 40%.

Notable is the distinction in the performance of eTranslation in the Audit domain. Its BLEU in this domain (23.23%, Table 2) was below average, however it performed best of all submitted MT systems in terms of Fluency×Adequacy (98.62%, Table 4), above Reference. Closer inspection revealed that the translations were very fluent and adequate but usually used vastly different phrasing than in the Reference, leading to very low BLEU scores.

Source:
In the vast majority of cases, the obligations arising from contracts for financing were properly implemented by the beneficiaries.
Reference:
Ve většině případů byly závazky vyplývající z podmínek podpory příjemci řádně plněny.
eTranslation: (**BLEU**: 9.24%)
Ve velké většině případů příjemci řádně plnili povinnosti vyplývající ze smluv o financování.
CUNI-DocTransformer: (**BLEU**: 41.21%)
V naprosté většině případů byly závazky vyplývající ze smluv o financování příjemci řádně plněny.

Figure 2: Example translations by eTranslation and CUNI-DocTransformer together with Source and Reference. N-grams present in Reference are underlined.

The example in Figure 2 shows activization (opposite of passivization) in the translation by eTranslation (*the beneficiaries fulfilled their obligations*) instead of (*obligations were fulfilled by the beneficiaries*). This resulted in much lower n-gram precision and BLEU score in general, even though the sentence is fluent and more adequate than both the Reference and translation by CUNI-DocTransformer.

3.4 Markable Phenomena and Systems

Table 5 shows an overview of types of markable phenomena with the average number of occurrences and Severity across systems. For all systems, *Terminology* and *Conflicting markables* had the most significant impact on the translation quality. These two categories clearly differ in Severity with markable conflicts being much more severe than terminological mistakes.

Inconsistency, *Typography* and *Disappearance* phenomena also heavily impacted the translation quality, although with varying distribution of Occurrences and Severity.

Reference differs from MT systems by having higher average Occurrence, but lower average Severity (first column in Table 5). Furthermore, the Reference had a higher number of *Inconsistence* occurrences, but with lower Severity. This means that most of these *Inconsitencies* were not actual errors. This is expected, as careful word choice variation improves the style and requires having an overview of previously used terms in the document.

Over-translation occurred rarely and in those cases, mostly in names (example shown in Figure 3). *Other grammar* manifested itself most severely in gender choice when translating sentences with person names without any gender indication from English to Czech. Similarly, *Style* was marked mostly in direct speech translation. The system used informal singular form addressing instead of plural. These two phenomena are shown in Figure 4.

Translation:
“Jak se opovažuješ?” Thunbergův projev OSN inspiruje nizozemské klimatické demonstranty

---

Figure 4: Example of bad translation style.

Noteworthy is the correlation between phenomena across systems. The highest values were between *Sense* and *Terminology* (0.89), *Terminology* and *Inconsistency* (0.83) and *Sense* and *Other grammar* (0.82). There is no straightforward explanation of this correlation except the obvious that a good system is good across all phenomena. The correlation in the last phenomena pair suggests that the *Other grammar* category is too coarse and contains other subcategories.

3.5 Markable Phenomena and Domains

The results of markable phenomena across different domains is shown in Table 6.

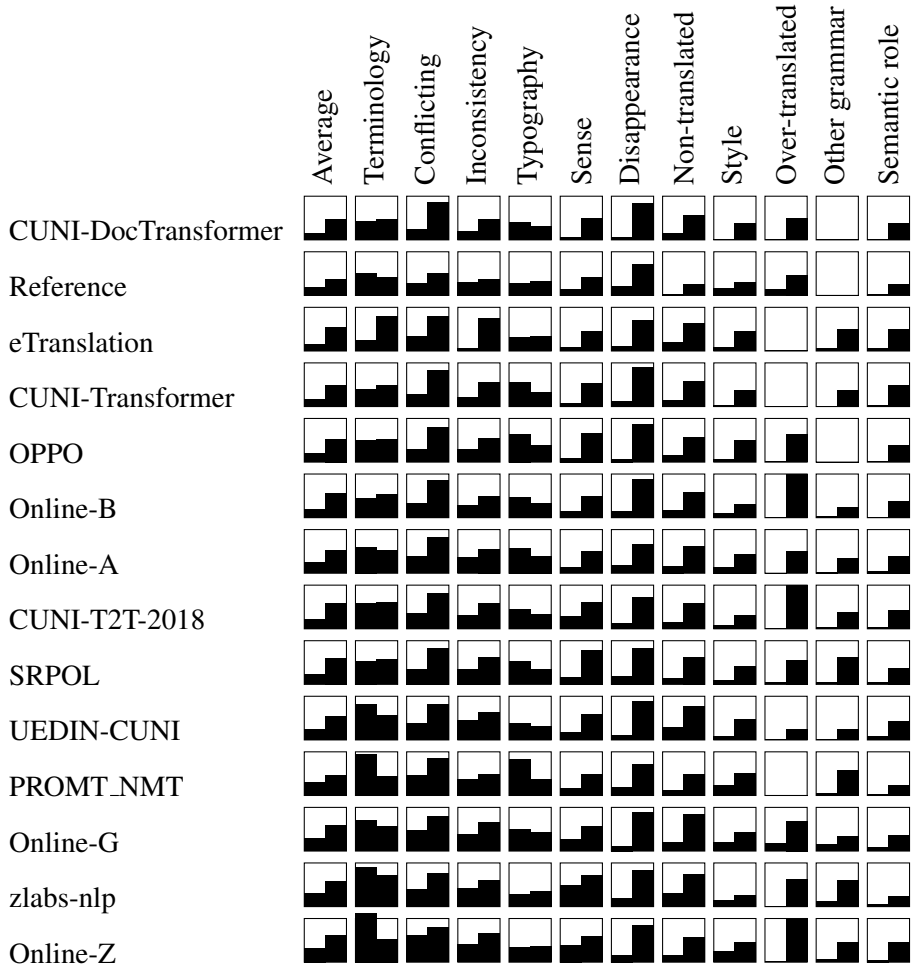

Table 5: Model results across 11 phenomena measured on markables together with their average. Each box is split into two bars: average Occurrence (left) and average Severity (right). Full left and right bars indicate occurrence in 20% of all markable instances and 100% Severity, respectively. Rows are sorted by Occurrence×Severity in the first column and columns, excluding *Average*, by the phenomena average Occurrence×Severity.

The second to last column is the correlation (across systems) between Occurrence×Severity and the BLEU score. The last column in Table 6 shows the correlation (across systems) between the two human scores: Occurrence×Severity and Fluency×Adequacy from the first phase of this experiment.

Since both BLEU and Fluency×Adequacy are positive metrics (the higher the score, the better the performance) and Occurrence×Severity is an error metric (the higher the number, the worse the performance), high negative correlations mean, that the metrics are mutually good performance predictors.

The strongest correlations are: *Conflicting* (-0.58), *Non-translated* (-0.55) and *Semantic role* (-0.41). Except for *Non-translated*, the reason is clear: BLEU is unable to check grammatical relations and never looks across sentences. We find the fact, that BLEU result was in agreement with error marking for these phenomena, to be positive.

Positive correlations (i.e. mismatches) were reached for *Disappearance* (0.28) and *Over-translated* (0.33), which is somewhat surprising because here BLEU *has* a chance to spot these errors from the technical point of view: shorter output could fire brevity penalty and missing terms where the exact wording is clear because they appear already in the source should decrease BLEU score. The overall correlation between Occurrence×Severity and Fluency×Adequacy is more significant than the correlation with BLEU. The most correlating variables are: *Sense* (-0.84), *Other grammar* (-0.84), *Terminology* (-0.81) and *Inconsistency* (-0.59).

Interesting is the markable phenomena *Disappearance* and *Sense* because of their high difference in correlations between BLEU and human score correlations.

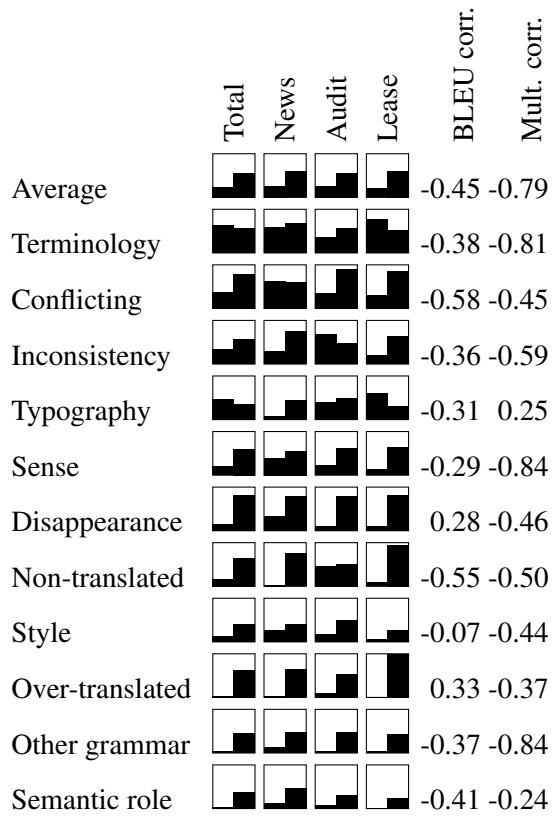

Table 6: Document domain average (across all systems) of markable phenomena. Sorted by Occurrence×Severity in the first column. Full left and right bars indicate occurrence in 20% of all markable instances and 100% Severity, respecively. The last two columns show correlation between Occurrence×Severity and BLEU and user ratings from Phase 1, respectively.

3.6 Annotator Agreement

We would like to bring attention to inter-annotator agreement for the second annotation phase. Table 7 lists the following metrics, which are computed pairwise and then averaged:

Plain inter-annotator agreement (IAA) reports the percentage of pairs of annotations where the two annotators agree that a given phenomenon was or was not present. IAA shows high numbers in all cases but it is skewed by the heavily imbalanced class distribution: most often, a phenomenon is not present; see the left sides of squares in the leftmost column in Table 6 for distribution reference.

Cohen's Kappa (Kappa), measured also pairwise, isolates the effect of agreeing by chance and reveals that a good agreement is actually reached only in the cases of *Disappearance*, *Terminology* and *Over-translated*, which are less ambiguous to annotate. It is unclear what is the reason behind the low Kappas, but we speculate that it is due to insufficient attention of the annotators: they would perhaps agree much more often that an error occurred but they were overloaded with the complexity of the annotation task and failed to notice on their own.

Phenomenon	IAA	Kappa	Corr.	Corr.+
Disappearance	0.90	0.43	0.52	0.06
Typography	0.95	0.20	0.55	-0.13
Sense	0.91	0.17	0.73	-0.09
Style	0.94	0.24	1.00	0.19
Terminology	0.90	0.41	0.07	-0.03
Inconsistency	0.88	0.13	0.18	-0.08
Non-translated	0.94	0.20	0.64	0.30
Conflicting	0.77	0.02	1.00	0.62
Other grammar	0.96	0.10	1.00	-0.35
Semantic role	0.97	-0.01	-	0.43
Over-translated	0.98	0.37	1.00	1.00

Table 7: Annotator agreement of Occurence marking (Inter Annotator Agreement and Cohen's Kappa) and agreement in Severity (two versions of Pearson Correlation) with respect to every markable phenomenon.

Plain Pearson Correlation (Corr.) was measured on Severities in instances where both annotators marked the phenomenon as present. This, however, disregards the disagreement in cases one annotator did not mark the phenomenon. For this, we also computed Corr.+, which examines all pairs in which at least one annotator reported Severity and replaces the other with zero.

We observe a big difference in the correlations. In cases where both annotators agreed that there was an error they tend to agree on the severity of the mistake, except *Terminology* and *Inconsistency*. If the cases where only one annotator marked the error are included, then the agreement on Severity is non-existent, except *Over-translation* and *Conflicting* translation.

3.7 Translation Direction

We also examined how the language translation directions affect the results. Most notable is CUNI-DocTransformer, which performs worse when translating into Czech. With only 0.01% higher Occurence of markable phenomena, the Severity increased by 20.81%. This is not something which we observed in other systems. The translation into Czech brought on average 0.01% higher Occurrence, but the Severity on average dropped by 3.99% when switching from English→Czech to Czech→English. The explanation supported by

the data is that in translation into English, CUNI-DocTransformer did not make any mistakes (or native Czech annotators did not detect them) and in translating into Czech, more issues were detected. Since the average Severity is measured across all phenomena, then the higher Severity in specific markable cases (Over-translated, Sense, Style and Disappearance) raised the overall average.

4 Annotation Examples

In the following figures (Figure 5, Figure 6 and Figure 7) we show annotated excerpts with BLEU, Fluency, Adequacy and markable phenomena severities. References are here to convey the Czech source segment meanings. They were not shown to the annotators. Examined markables are underlined.

Reference:
This Supplement No. 1 is written and signed in 2 (in words: two) copies, each of which is valid for the original.
Translation:
This Appendix 1 is drawn up and signed in two copies, each of which has the validity of the original.

BLEU: 23.59%, **Fluency:** 1, **Adequacy:** 0.9
Disappearance: 1

Figure 5: Example sentence markable (in words) annotation from Czech Lease document, translated by OPPO.

The example in Figure 5 focuses on intentional, key information duplication (for clarity and security reasons) of the number of signed copies. This duplication was however omitted in the translated output. The output is otherwise fluent and even received higher fluency than the Reference, which has an average fluency of 0.8.

Noteworthy is also another markable visible in the same figure, namely the referred section name: Appendix 1. Even though this word is different from the markable in the Reference: Supplement No. 1, it is used consistently across the whole document. Another variant of the translation is: Amendment No. 1. OPPO, together with Online-Z are the only systems which translated this markable correctly and consistently. Most of the systems (zlabs-nlp, Online-A, Online-B, Online-G, UEDIN-CUNI, CUNI-T2T-2018) switched inconsistently between the lexical choice. Other systems (SRPOL, eTranslation, CUNI-Transformer, CUNI-DocTransformer) were consistent in the main word choice, but not either in capitalization or number (e.g. Appendix No. 1 and Appendix 1).

Word variability (i.e. inconsistency) is often used to make the text more interesting, but in this context, it is vital that the term is translated consistently. Most of the systems, which outperformed even the Reference, made a severe error in this case.

Reference:
The most expensive item to be paid before the Grand Prix is the annual listing fee. This year, the fee was around 115 million Czech crowns. "Masses of people who come to Brno to see the Grand Prix spend money here for their accommodation, food and leisure activities, which should more or less balance out the cost associated with the organization of the event, including the listing fee," economist Petr Pelc evaluated the situation.
Translation:
The most expensive item is a breakdown fee every year before the Grand Prize. This year was about a hundred fifteen million crowns. "Mass of people who will come to Brno at the Grand Prix will spend money on accommodation, food or entertainment, which should more or less balance the costs associated with organizing the event, including the unifying fee," the economist Petr Pelc assessed.

BLEU: 26.59%, **Fluency:** 0.6, **Adequacy:** 0.4
Terminology: 1, **Sense:** 1, **Inconsistency:** 1

Figure 6: Example sentence markable (listing fee) annotation from Czech News document, translated by CUNI-T2T-2018.

Figure 6 shows a listing fee incorrectly translated as breakdown and unifying fee. This markable translation is interesting in the fact that systems were again very inconsistent with the markable translation choice. The wrong lexical choices were: landing, paving, parking, refill, landfill, security, zalistovacího, leasing, drop-in, back-up, reforestration, clearance, referral, padding fee and stamp duty. Good translations were: listing and registration fee.

Online-B and CUNI-DocTransformer made good and consistent lexical choices. SRPOL made good lexical choices but switched between them.

In this instance, this would not be an error, because consistency is not vital for interpreting the text.

The translation by CUNI-T2T-2018 in Figure 6 is not wrong only because of this markable translation choice, but also by poor fluency. The BLEU score, however, does not suggest, that there is anything fundamentally wrong with the translated segment despite the meaning being distorted.

Reference:
In Art. III of the Sublease agreement, entitled "Term of the Lease," the tenant and the lessee agreed that the apartment in question would be rented to the tenant for a fixed period from 13th May 2016 to 31st December 2018.
Translation:
In art. III of the apartment lease agreement, called "sublease period", the tenant and the tenant agreed that the apartment in question will be left to the tenant for use for a fixed period from 13. 5. 2016 to 31. 12. 2018.

BLEU: 31.95%, **Fluency:** 0.7, **Adequacy:** 0.5
Terminology: 0.5, **Sense:** 0.25, **Conflict:** 1,
Other grammar: 0.25

Figure 7: Example sentence markable (lessee) annotation from Czech News document, translated by Online-G.

The last example, in Figure 7, concerns itself with conflicting markables. In this case, two distinct markables (tenant and lessee) were merged into one translation tenant. This is a very fundamental error because, in the Lease agreement, these two markables refer to the two parties, which enter the contract.

Again, the BLEU does not suggest that anything is wrong with the translation. It could be even higher (51.06%) were it not for the localized date format in the Reference.

5 Conclusion

In this article, we compared three approaches to document translation evaluation. We saw that non-expert annotators rate most MT systems higher than Reference with Fluency and Adequacy, but Reference ranks better than most of them when inspecting markable phenomena and their Severity. Inspecting specific instances in detail, we found out that MT systems made errors in terms of markables, which no human translator would do.

Relating the current observation with the impression last year, we conclude that annotators lacking in-depth domain knowledge are not reliable for annotating on the rather broad scales of Fluency and Adequacy but they are capable of spotting term translation errors in the markable style of evaluation. This is important news because expert annotators can not be always secured. Unfortunately, the inter-annotator agreement remains generally low, possibly due to a high cognitive load with many systems annotated.

We further examined these markable phenomena and showed that especially *Sense*, *Other grammar* and *Terminology* kinds of errors negatively influence the Fluency and Adequacy the most. For BLEU the variables of highest importance were *Non-translated* and *Conflicting* errors.

In future work, we would like to examine more of the kinds of markable errors in modern MT systems and their influence on the translation quality. This description could then help researches focus on specific parts of their MT systems.

Furthermore, we would like to explore possible automated metrics, which would help in determining whether the document meaning remained intact with respect to markables.

Annotating markables appears to be easier for human annotators and more reliable for non-expert ones, and the results gave us more insight into the systems' performance than the Fluency-Adequacy method.

Translating Similar Languages: Role of Mutual Intelligibility in Multilingual Transformers

Ife Adebara **El Moatez Billah Nagoudi** **Muhammad Abdul Mageed**
Natural Language Processing Lab
University of British Columbia
{ife.adebara,moatez.nagoudi,muhammad.mageed}@ubc.ca

Abstract

We investigate different approaches to translate between similar languages under low resource conditions, as part of our contribution to the WMT 2020 Similar Languages Translation Shared Task. We submitted Transformer-based bilingual and multilingual systems for all language pairs, in the two directions. We also leverage back-translation for one of the language pairs, acquiring an improvement of more than 3 BLEU points. We interpret our results in light of the degree of mutual intelligibility (based on Jaccard similarity) between each pair, finding a positive correlation between mutual intelligibility and model performance. Our Spanish-Catalan model has the best performance of all the five language pairs. Except for the case of Hindi-Marathi, our bilingual models achieve better performance than the multilingual models on all pairs.

1 Introduction

We present our findings from our participation in the WMT 2020 Similar Language Translation shared task, which focused on translation between similar language pairs in low-resource settings. Similar languages share a certain level of mutual intelligibility that may aid the improvement of translation quality. Depending on the level of closeness, certain languages may share similar orthography, lexical, syntactic, and or semantic structures which may make translation more accurate.

The level of mutual intelligibility is such that speakers of one language can understand another language without prior instruction in that other language. They can also communicate without the use of a lingua franca which is a link or vehicular language used for communicating between speakers of different languages (Gooskens, 2007). It is important to mention that, sometimes, the level of intelligibility varies in both directions. For instance, Slovene - Croatian intelligibility is said to be asymmetric such that speakers or Slovene can understand spoken and written Croatian better than speakers of Croatian understand Slovene (Golubović and Gooskens, 2015).

Machine translation of similar languages has been explored in a number of works (Hajic, 2000; Currey et al., 2016; Dabre et al., 2017). This can be seen as part of a growing need to develop models that translate well in low resource scenarios. The goal of the current shared task is to encourage researchers to explore methods for translating between similar languages. We also view the shared task as useful context for studying interaction between degrees of similarity and mutual intelligibility on the one hand, and model performance on the other hand. We explore the use of bilingual and multilingual models for all the 5 shared task language pairs. We also perform back-translation for one language pair.

In the remainder of this paper, we discuss related literature in Section 2. We explain the methodology which includes a description of the Transformer model, back-translation and beam search in Section 3. In Section 4, we describe the models we developed for this task and we discuss the various experiments we perform. We also describe the architectures of the models we developed. Then we discuss the evaluation procedure in Section 6. Evaluation is done on both the validation and test sets. We conclude with discussion and the insights gained from this task in Section 7.

2 Related Work

Translation between similar languages has recently attracted attention. Different approaches have been adopted using state-of-the-art techniques, methods, and tools to take advantage of the similarity between languages even in low resource scenarios. Approaches that have been effective for other ma-

Proceedings of the 5th Conference on Machine Translation (WMT), pages 381–386

chine translation tasks have proven to achieve success in the context of similar language translation as well.

NMT models, specifically the Transformer architecture, has been shown to perform well when translating between similar languages (Baquero-Arnal et al., 2019; Przystupa and Abdul-Mageed, 2019). The use of in-domain data for fine-tuning has also proven to be of remarkable benefit for this task. This problem has also been tackled both by using character replacement to leverage the orthographic and phonological relationship between closely related mutually intelligible language pairs (Chen and Avgustinova, 2019). A new approach was also introduced for this task using a two-dimensional method that assumes that each word of the target sentence can be explained by all the words in the source sentence (Baquero-Arnal et al., 2019).

Within the realm of MT for low resource languages, recent work has focused on translation using large monolingual corpora due to the scarcity of parallel data for many language pairs (Lample et al., 2018, 2017; Artetxe et al., 2018b). These approaches have leveraged careful initialization of the unsupervised neural MT model using an inferred bilingual dictionary, sequence-to-sequence language models, and back-translation to achieve remarkable results. The bilingual dictionary is built without parallel data by using an unsupervised approach to align the monolingual word embedding spaces from each language (Conneau et al., 2017; Artetxe et al., 2018a). Since parallel data is not available in sufficiently large quantities, back-translation is used to create pseudo parallel data. The monolingual data of the target language is translated into the source using an existing translation system (e.g., one trained with available gold data). The output is then used to train a new MT model (Sennrich et al., 2015a). Weak supervision caused by back-translation results in a noisy training dataset. This eventually can affect translation quality.

More recent works adopt different approaches to manage noise in back-translation. For instance, phrase based statistical MT models are introduced as a posterior regularization during the back-translation process to reduce the noise and errors of the data generated (Ren et al., 2019). Another method (Artetxe et al., 2019b) uses cross lingual word embeddings incorporated with sub-word information. The weights of the log-linear model is then tuned through an unsupervised process and the entire system is jointly refined in opposite directions to improve performance. This method outperforms previous SOTA model with about 5-7 BLUE points. A re-scoring mechanism that re-uses the pre-trained language model to select translations generated through beam search has also been found to improve fluency and consistency of translations (Liu et al., 2019). Yet another approach, combines cross-lingual embeddings with a language model to make a phrase-table (Artetxe et al., 2019a). The resulting system is then used to generate a pseudo parallel corpus with which a bilingual lexicon is derived. This approach can work with any word or cross-lingual embeddings techniques.

3 Methodology

Motivated by the success of Transformers and back-translation, we develope a sequence-to-sequence approach using the Transformer architecture perform back-translation for one language pair. For decoding, we use Beam Search (BS). BS is an heuristic decoding strategy based on exploring the solution space and selecting a sequence of words that maximize the overall likelihood of the target sentence. During the translation, we hold a beam of β sequences (*beam size*) which are iteratively extended. At each step, β words are selected to extend each of the sequences in the beam, so the output is β^2 candidate sequences (hypotheses), we retain only the β highest score hypotheses for the next step (top-β candidates) (Koehn, 2009). In all our experiments we use beam size of 5 whilst decoding.

3.1 Transformer

Our baseline models are based on the Transformer architecture. A Transformer (Vaswani et al., 2017) is a sequence-to-sequence model that does not have the recurrent architecture present in Recurrent Neural Networks (RNNs). It uses a positional encoding that can remember how sequences are fed into the model. These positions are added to the embedded representation (n-dimensional vector) of each word. Transformers have been shown to train faster than RNNs for translation tasks.

The encoder and decoder in a Transformer model have modules that consist mainly of multi-head attention and feedforward layers. The attention mechanism is based on a function that operates on Q (*queries*), K (*keys*), and V (*values*). The query

is a vector representation of one token in the input sequence, K refers to the vector representations of all the tokens in the input sequence. More information about the Transformer are in (Vaswani et al., 2017).

3.2 Back-translation

We perform back-translation using the monolingual model developed for the Croatian-Slovene (HR-SL) language pair. We use the best HR-SL model checkpoint that acquire the highest BLEU score on the DEV set to translate the monolingual HR data. This produces synthetic Slovene (SL) data which we then use as the source language while the original monolingual data is used as target when training the SL-HR model. We combine this data with the initial training data.

Due to time constraints, we used only a subset of the monolingual data with a beam size of 5.

3.3 Jaccard Similarity

Jaccard similarity compares similarity, diversity, and distance of data sets (Niwattanakul et al., 2013). It is calculated between two data sets in our case two languages) A and B by dividing the number of features common to the two sets (their intersection) by the union of features in the two sets, as in (1) below:

$$J(A,B) = \frac{|A \cap B|}{|A \cup B|} \quad (1)$$

We use tokens, identified based on white space, as features when we calculate Jaccard.

4 Experiments

4.1 Model Architecture

Our neural network models are based on the Transformer architecture (as described in Section 3) implemented by Facebook in the Fairseq toolkit. The following hyper-parameter configuration was used: 6 attention layers in the encoder and the decoder, 4 attention heads in each layer, embedding dimension of 512, maximum number of tokens per batch was set to $4,096$, Adam optimizer with $\beta 1 = 0.90$, $\beta 2 = 0.98$, dropout regularization was set to 0.3, weight-decay was set at 0.0001, $label - smoothing = 0.1$, variable learning rate set at $5e-4$ with the inverse square root, lr-scheduler and $warmup - updates = 4,000$ steps. We used the label smoothed cross-entropy criterion, and gradient clip-norm threshold was set to 0.

5 Data

We used all the parallel data for all language pairs http://www.statmt.org/wmt20/similar.html. The task was constrained so we did not add any additional data to develop our models. We used the monolingual data for the SL-HR language pair for back-translation. Table 2 shows the size of the data in terms of the number of sentences and words for each language pair while Table 1 shows example source and corresponding outputs from our bilingual and multilingual models for each language pair. We also calculated the jaccard similarity for the training data we used for the tasks. "Jaccard similarity" measures the similarity between two text documents by taking the intersection of both and dividing it by their union. Linguists measure these intersections (Oktavia, 2019; Gooskens and Swarte, 2017) between languages to determine the level of mutual intelligibility as well as classify languages as dialects of the same language or different languages. We calculated Jaccard similarity for each language pair.

5.1 Pre-processing

Pre-processing was by a regular Moses toolkit (Koehn et al., 2007) pipeline that involved tokenization, byte pair encoding and removing long sentences. We applied Byte-Pair Encoding (BPE) (Sennrich et al., 2015b) operations, learned jointly over the source and target languages. For each language pair, we used 32k split operation for subword segmentation (Sennrich et al., 2016b). We run experiments with Transformers under three settings, as we explain next.

5.2 Models

We develop both bilingual and multilingual models using gold data for all pairs. For one pair, we also use back-translation with one bilingual model. We provide more details next.

5.2.1 Bilingual Models

In this setting, we build an independent model for each language pair. We develop models for both directions for all language pairs, thus ultimately creating 12 models (6 for each direction). We train each model on 1 GPU for 7 days.

5.2.2 Multilingual Models

We develop two multilingual models that translates between all languages; a model for each direction (2 models overall) (Johnson et al., 2017). We add

Model	Pair	Sentence	Translation
Bilingual Model	Es-Ca	Diseña stickers para soñar	Dissenya stickers per soyir
		Mueva el diez de corazones al nueve de corazones .	Mobles el deu de garrons al nou de garrons .

Table 2: Number of sentences and words for the training data used for each language pair

a language code representing the target language as the start token for each line of the source data. We train each model on 4 GPUs for 7 days. We use the same hyper-parameters values set for the bilingual models. Multilingual models enable us to determine the impact of learning similar languages with a shared representation.

5.2.3 Bilingual Model with Back-translation

For the third approach, we combine back-translation with the bilingual translation model for the SL-HR language pair. We incorporated the monolingual data to do this. This was influenced by report (Sennrich et al., 2016a) in literature on the significant improvement of translation quality when monolingual data is incorporated into training data through back-translation. We were able to test the effect of back-translation on one model.

6 Evaluation

We evaluated both the DEV and TEST sets. We used the best-checkpoint metric with BLEU score to evaluate the validation set at each iteration. We used a beam size of 5 during the evaluation . We de-tokenized from BPEs back into words.

6.1 Evaluation on DEV set

We report the results on the DEV sets for each language pair in Table 3. These models were trained without the monolingual data except the SL-HR pair with the asteriks.

Pair	Bilingual Models	Multiling. models
hi-mr	12.14	16.35
mr-hi	10.63	01.02
es-ca	74.85	16.13
ca-es	74.24	64.57
es-pt	46.71	26.41
pt-es	41.12	05.81
∗sl-hr	36.89	-
sl-hr	33.28	09.25
hr-sl	55.51	07.94
sl-sr	40.80	32.80
sr-sl	39.80	06.97

Table 3: Evaluation in BLEU on the development set for the different language pairs. The asteriks shows the model with back-translation

The bilingual models outperform the multilingual models for all language pairs except the hi-mr language pair.

6.2 Evaluation on TEST

In order to evaluate the test data, we removed the byte-pair code from the test set. We used the fairseq-generate mode while translating the test set. We show results on the test set in Table 4.

Pair	Bilingual Models	Multiling. models
hi-mr	0.49	-
es-ca	41.74	8.49
ca-es	45.23	45.86
es-pt	23.35	17.06
pt-es	24.26	21.55
*sl-hr	20.92	22.26
hr-sl	14.94	7.37
sl-sr	14.7	20.18
sr-sl	19.46	11.37

Table 4: The BLEU scores for some of the models on the test set. The language pair with the asterisks has back-translation [1]

6.3 Discussion

We used the Jaccard similarity to measure the level of mutual intelligbility. Figure 1 shows a positive correlation between the BLEU scores and the Jaccard similarity between each language pair. [2] This relationship hold both for the bilingual and multilingual models. One exception is the Slovene-Serbian pair (SL-SR) where higher similarity does not translate into higher BLEU. For example, the SL-SR BLEU is below the SL-HR BLEU even though the latter pair has a higher similarity score. Interpreting Jaccard to mean mutual intelligibility, our findings imply a higher intelligibility is correlated with higher BLEU scores. However, there is a need to further investigate this relationship due to the SL-SR we observe.

7 Conclusion

We described our contribution to the WMT2020 Similar Languages Translation Shared Task. We developed both bilingual and multilingual models for all pairs, in both directions. We showed back-translation to help improve performance on one pair. We also showed how mutual intelligibility between a pair of languages (measured by Jaccard similarity) positively correlate with model performance (in BLEU). Future work can focus on exploiting other similarity metrics and providing a more in-depth study of mutual intelligibility between similar languages and how it interacts with MT model performance both in bilingual and multilingual models. The utility of back-translation on pairs we have not studied can also be fruitful.

[2]We multiplied the jaccard similarity by 100 to reduce the range of values on the y axis.

Abstract

This paper illustrates our approach to the shared task on similar language translation in the fifth conference on machine translation (WMT-20). Our motivation comes from the latest state of the art neural machine translation in which Transformers and Recurrent Attention models are effectively used. A typical sequence-sequence architecture consists of an encoder and a decoder Recurrent Neural Network (RNN). The encoder recursively processes a source sequence and reduces it into a fixed-length vector (context), and the decoder generates a target sequence, token by token, conditioned on the same context. In contrast, the advantage of transformers is to reduce the training time by offering a higher degree of parallelism at the cost of freedom for sequential order. With the introduction of Recurrent Attention, it allows the decoder to focus effectively on order of the source sequence at different decoding steps. In our approach, we have combined the recurrence based layered encoder-decoder model with the Transformer model. Our Attention Transformer model enjoys the benefits of both Recurrent Attention and Transformer to quickly learn the most probable sequence for decoding in the target language. The architecture is especially suited for similar languages (languages coming from the same family). We have submitted our system for both Indo-Aryan Language forward (Hindi to Marathi) and reverse (Marathi to Hindi) pair. Our system trains on the parallel corpus of the training dataset provided by the organizers and achieved an average BLEU point of 3.68 with 97.64 TER score for the Hindi-Marathi, along with 9.02 BLEU point and 88.6 TER score for Marathi-Hindi testing set.

1 Introduction

This paper focuses on establishing a neural machine translation model using Encoder-Decoder architecture to translate between Hindi-Marathi sentence pairs. We are utilizing an attention mechanism approach by employing the combination of recurrence based RNN Encoder-Decoder layers (Cho and et al., 2014) and latest machine translation technique the Transformers (Vaswani et al., 2017) to address the complexity of WMT-20 similar language data-set (Hindi-Marathi). The motivation behind combining RNN and Transformer architecture is taken from the paper (Huang et al., 2020) to utilize the benefits of both. The formulated machine translation system has numerous applications. It can be used in advertising campaigns to reach native users. The media industry can employ this technology for generating subtitles and broadcasting multilingual news to cover a wide range of native subscribers of a region. Moreover, these systems can provide native vernaculars in social media to increase the activities of indigenous individuals of a native language. Additionally, Search engines can also adopt this method to display relevant results to clients in their region-specific native language.

The paper is composed of three further sections. The second section will display our proposed approach to solve the problem of Hindi-Marathi translation, followed by a discussion on designed experiments for training the model and mechanism for generating the results. Lastly, we will illustrate contributions and future work.

2 Methodology

The paper proposes a novel approach called Attention Transformer shown in Fig. 1 to translate between Hindi and Marathi text. In the figure, two encoder and decoder layers are illustrated. The initial N Encoder-Decoder layers contain RNN units in the form of LSTMs, which get stacked on top of each other. First, the initial encoder layer processes the tokenized input and generates a context vec-

Proceedings of the 5th Conference on Machine Translation (WMT), pages 387–392

tor. The initial decoder layer consumes the context vector generated by the neighboring encoder layer. Plus, it takes the target output as its input while training by utilizing the concept of teacher force training (Goyal and et al., 2016). Next, the processed outputs of both the initial Encoder-Decoder layer gets presented as input to the transformer model.

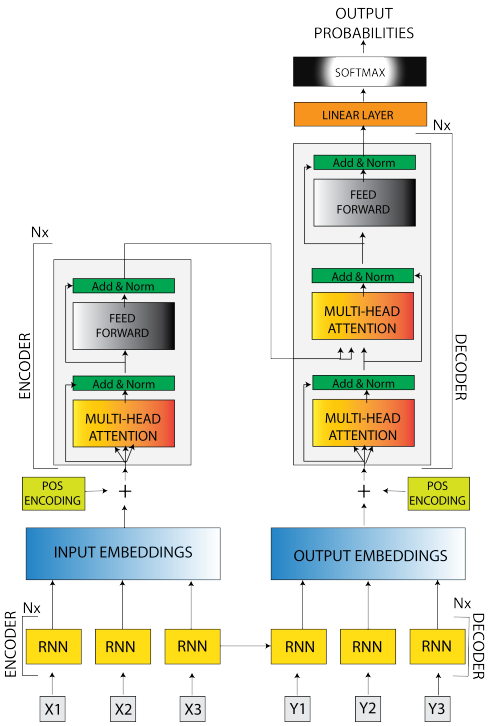

Figure 1: This Figure shows bird's-eye view of the proposed Attention Transformer Model

In the Transformer model, we can observe the second Encoder and Decoder layer stacked on the top of positional input-output embedding layers. In the Transformer, the positional input-output embedding layer receives the output of the initial Encoder-Decoder layer as its input. The role of the positional embedding layer is first to convert its input, which comes from the previous RNN based Encoder-Decoder layer into d-dimensional space where d is the output size of the embedding layer and add a positional encoding vector to it. As a result, all similar words relative to their positions in the training sentences will get cluster together. The working of the positional encoding vector is presented in the paper (Vaswani et al., 2017). Next, the outputs of the positional embedding layer get passed to Encoder-Decoder layers of Transformer. An individual Encoder-Decoder layer of Transformer contains a multi-head attention mechanism followed by a feed-forward layer, and a Transformer can have N number of such layers. The multi-head attention mechanism and feed-forward layer works, as illustrated in the paper (Vaswani et al., 2017), and their outputs are normalized. To train the model, we can apply the teacher forcing mechanism while during testing, a start token is initially required for the decoder to start the decoding process. After that, we can let the decoder to generate the output tokens in a loop by utilizing its current output as input to the next time frame until it produces the end token.

3 Experimental Studies

We have used Two human-level translation evaluation criteria, which are BLEU (Papineni and et al., 2002) and TER (Snover and et al.) scores and two general evaluation metrics that are Sparse Categorical Accuracy and Mean Loss. This section will first discuss the preparation of training data-set and baseline models, followed by training procedures plus their outcomes. And then, we will move towards explaining the results of the testing procedure. It is important to note that all experiments given below are performed using TPU with 180 TFlops, and 64 GB High Bandwidth Memory (HBM) provided by Google Colab, plus an implementation of the experiment is located in the Colab notebook (implementation).

3.1 *Data-set*

Initially, we have a Hindi-Marathi parallel training corpus of 44,685 sentence pairs. We have applied a simple rule to filter out all sentence pairs having the length higher than 24 words. After using this filtering rule on the data-set, we are left with 35,215 sentence pairs on which we have applied 80%-20% split to extract out training and development data. We have separated 100 records from the dev-set, and treat it as unseen data to perform a comparison with the baseline models. The table 1 shows the division of the data-set.

The reason for the maximum length based filtration of the data-set is with an increase in the maximum length of a sentence in the data-set, the complexity of the model increases, hence the training time increases. Although vocabulary size and hyper-parameters of the model also play a significant role in the training time per Epoch. Plus, we are motivated to keep our model simple as much as possible because the quality of the predicted translation gets affected, and it becomes difficult to

DATA-SET CONTENTS	
Data-set total sentence pairs	44,685
Filtered data-set sentence pairs	35,215
Training set sentence pairs	28,172
Development set sentence pairs	6,943
Records for comparison with baseline models	100
Hindi vocabulary size in filtered data	31,417
Marathi vocabulary size in filtered data	53,639

Table 1: The table shows the division of the data-set

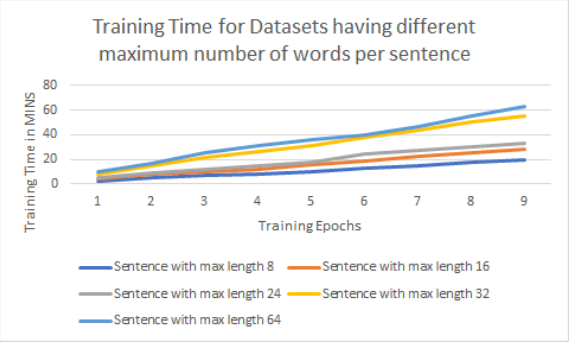

Figure 2: The figure shows line graphs illustrating the training time on filtered data-sets having different lengths of maximum words in a sentence.

debug the model as it grows more complex.

3.2 *Baseline Models*

We have selected the Bahdanau (Bahdanau and et al., 2014) and Transformer (Vaswani et al., 2017) model as a baseline model to compare the performance of our model. We have used their TensorFlow implementation officially given at (TensorFlow, a) and (TensorFlow, b). In our experiment, we have extracted 100 records from the dev-data, which serves as unseen data and helps us to compare the goodness of our proposed model with the selected baseline models. We have trained the model on the Marathi-Hindi dataset, with the mentioned parameters in TensorFlow documentation, and recorded that the Bahadanau model gets an average BLEU score of 0.13, while the transformer gets an average BLEU score of 20.

3.3 *Selecting Hyper-parameters*

The first essential hyper-parameter is to decide the maximum number of words a source or target sentence can have in a single given instance of a training sentence. However, it's a fantasy to develop a model that handles infinite words in the training instance. But as a result, it leads to infinite training time, which is undesirable. We have run the attention transformer model with the top 1000 records after filtering the dev-set with the various maximum number of words a source and target sentence can have and recorded their training time as shown in the chart below. In Fig 2, we can notice that increment in the maximum number of words a sentence can have produces a drastic impact on training time. We have selected 24 as the maximum number of words a sentence can have in our data-set to achieve comparable performance in practical training time.

After filtering the data-set based on the maximum number of words, a sentence can have. The next essential thing is to choose an appropriate batch size for the model. We have executed the Attention transformer model with different batch sizes on dev-set and noted their impact on training time per epoch. The Fig. 3 illustrates that the increment in batch size helps to reduce training time up to an extent after that it reduces the efficiency of the model. We have selected 16 as batch size, as it gives minimum training time per epoch for the model.

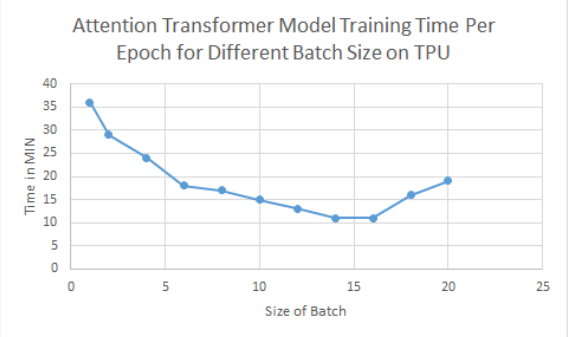

Figure 3: The figure shows a line graph illustrating the training time per epoch for different batch sizes.

In addition to that, to keep the training time of Attention Transformer practical, with a TPU of 180 TFlops and 64 GB High Bandwidth Memory (HBM). We have set the number of initial RNN based Encoder-Decoder layers to one and the number of the second Transformer Encoder-Decoder layer to two. Plus, the number of attention heads in the multi-head attention layer of the Transformer encoder-decoder layer is set to 8, and all other hyper-parameters for transformer model are kept as suggested in the paper (Vaswani et al., 2017).

3.4 *Training the Model*

In training, we have not augmented the original form of the given sentences in the data-set. In the pre-processing step, we have only removed punctuation from the sentences and fed the filtered data to the model, which sums up to 35,215 sentence pairs. We have used the selected hyper-parameters from previous subsections to train the model, which are obtained by optimizing dev data. In addition to that, to keep track of our models' performance, we have used the Sparse Categorical Cross Entropy function as our loss function for evaluating training predictions, which is an integer version of the Categorical Cross Entropy function the details can be observed in the notebook (implementation)

3.5 *Dealing with Over-Fitting and Unseen Vocabulary at Test Time*

To save the model from overfitting, we have kept the training procedure straight-forward by applying a simple rule to train the model until it provides a BLEU score of 0.7 or the performance of BLEU score asymptotes after ten epochs. While training, we have collected average BLEU scores, TER score, Accuracy, and Mean Loss across batches over an epoch to track the performance of the model as shown in (implementation).

Moreover, to deal with new input vocabulary at test time, we have employed a simple trick by generating a miscellaneous token at the time of tokenization. The miscellaneous token gets included in the vocabulary of the model at train time. And the model learns to deal with this token based on its neighbors. During test time, while tokenization, if the input sentence contains any unseen vocabulary, then we exchange that word with the miscellaneous token.

3.6 *Comparison With Baseline Model*

We have trained the baseline models and our proposed attention transformer model on the Marathi-Hindi data-set at the end of each epoch, we have recorded the training time. This per epoch training time will allow us to measure the quickness in the model to finish a training epoch. Fig. 4 below states the comparison of cumulative training time of all three models. It can be seen clearly that the Bahdanau model takes a huge amount of training time as compared to the other two models. We were able to run only 10 epochs for the Bahdanau model in approximately 9 hours. On the other hand Transformer and Attention, Transformer models are very quick, it takes approximately 7 minutes to train an epoch of both the models. However, over the time it can be seen in the graph that the baseline Transformer model is slightly quicker than our proposed Attention Transformer model.

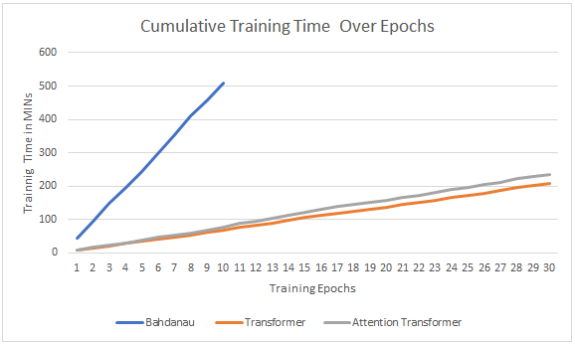

Figure 4: The figure shows comparison of cumulative training time of Bahdanau, Transformer and Attention Transformer model.

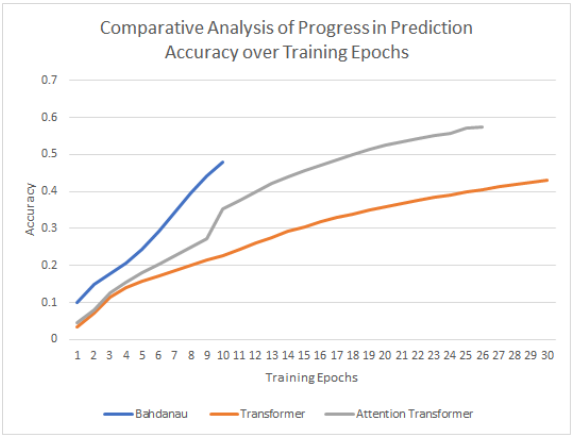

Figure 5: The figure shows comparison of progress in Sparse Categorical Accuracy as we continue to train the Bahdanau, Transformer and Attention Transformer model.

Next, to measure the progress in translation performance as we continue to train the model, we have recorded average Sparse Categorical Accuracy, BLEU score, Sparse Categorical cross entropy loss, and TER scores at the end of each epoch as shown in Fig. (5, 6, 7, 8) respectively. This track of per epoch training performance helps us to visualize the progress of the model in learning the translation probability distribution, plus we can also utilize this information to find out the most active model that fits translation distribution in the least number of epochs.

In the Fig. 5 and 6, we can notice that the Bah-

danau model is quickest to adapt translation probability distribution compared to other models as it has shown approximately exponential increment in accuracy and BLEU scores over the initial training epochs. The transformer model is following a relatively linear path in learning the probability distribution.

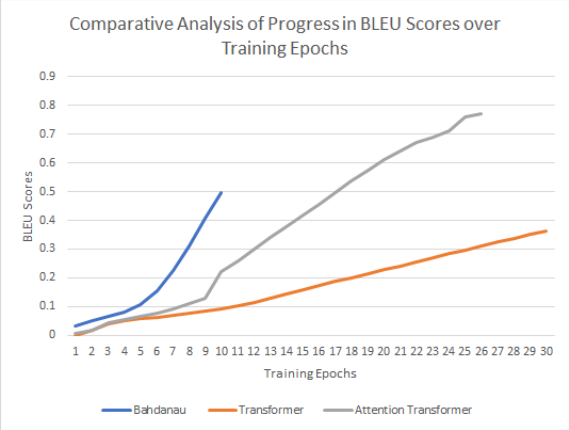

Figure 6: The figure shows comparison of progress in BLEU score as we continue to train the Bahdanau, Transformer and Attention Transformer model.

The reason behind the wining performance of the Bahdanau model is it's inherent recursive nature to model the sequence to sequence tasks, which helps it to learn the positional order of the given sequence. The Transformer lacks this recursive nature and uses a sinusoidal positional encoding scheme to get the awareness of the position of a word in a sentence, which is not as effective as Bahdanau's inherent recursive nature. But this recursive nature hinders the Bahdanau model to exploit parallelism due to this Bahdanau model takes more time to finish a training epoch as compare to the Transformer model.

The Attention Transformer takes the benefits of both the Bahdanau and the Transformer model. The initial layer of RNN helps the Attention Transformer to learn the positional order of the given sequence, plus the stacked Transformer above it allows the Attention Transformer to apply maximum parallelism. In the Fig. 5 and 6, we can notice that the Attention Transformer has given a relatively intermediary performance as compare to the other two models because we have kept the number of RNN and Transformer layers almost equal. If we increase the number of RNN layers in the Attention Transformer model it will start behaving more like the Bahdanau model likewise, if we increase the number of transformer layers then it will act more like the Transformer model.

Similarly, we can use the same argument to reason about the displayed behavior of the performance of the Bahdanau, Transformer, and Attention Transformer model in Fig. 7 and 8

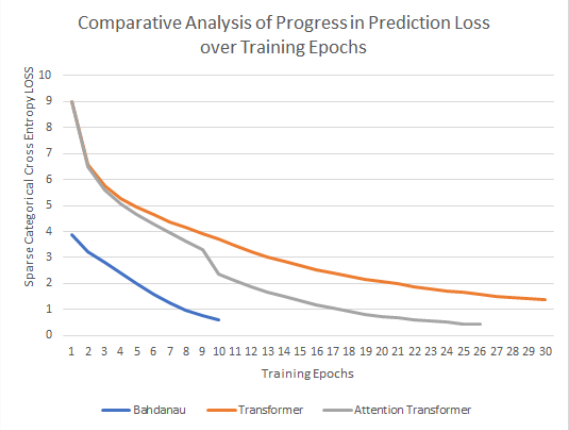

Figure 7: The figure shows comparison of decrements in loss as we continue to train the Bahdanau, Transformer and Attention Transformer model.

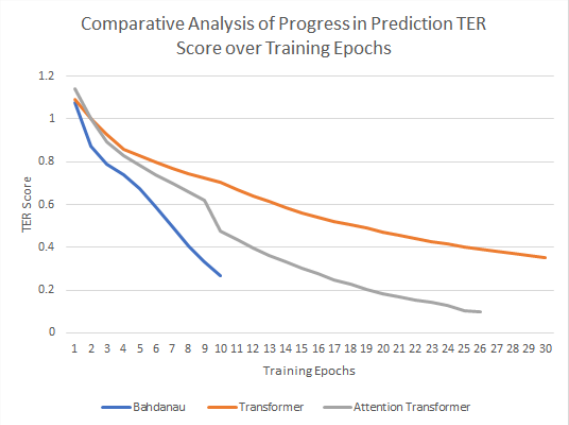

Figure 8: The figure shows comparison of decrements in TER score as we continue to train the Bahdanau, Transformer and Attention Transformer model.

Finally, we have utilized the trained Bahdanau, Transformer, and Attention Transformer model to translate 100 unseen records from Marathi to Hindi, which we have initially separated from the dev dataset. The Fig. 9 below displays the performance of the trained models on the scale of 0-1 BLEU points, the Bahdanau model fails to capture the distribution of unseen data, while the Transformer model performs relatively good. Attention Transformer gives comparatively better performance on average as it shows high BLEU scores for many of the instances.

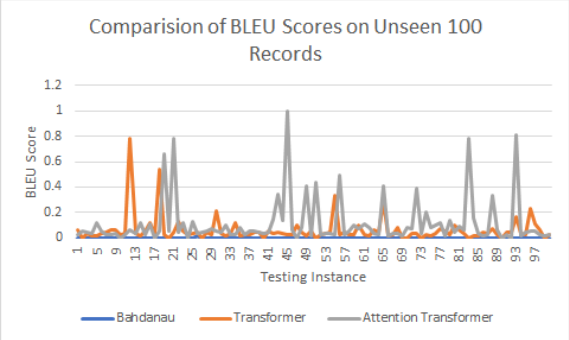

Figure 9: The figure shows comparison of calculated BLEU scores on the scale of 0-1 from the predictions of Bahdanau, Transformer and Attention Transformer model on the unseen 100 records which we have separated from the development data.

3.7 *Testing Results*

We have developed two instance models of Attention Transformer using the procedure mentioned above for both predicting Marathi sentences when Hindi sentences are given as input and predicting Hindi sentences when Marathi sentences are provided as input. We have achieved BLEU points of 3.68 and a TER score of 97.64 for the Hindi-Marathi test pair. Plus, BLEU points of 9.02 and the TER score of 88.68 for the Marathi-Hindi test data-set.

4 Conclusion

This paper has presented a supervised deep neural translation-based approach called Attention Transformer as a tool to perform translation between similar pair of languages (Hindi-Marathi). We have developed a novel Neural Translation method called Attention Transformer to transmute from Hindi source to Marathi and vice-versa by combining the classical recurrence based encoder-decoder approach and Transformers working mechanisms. All supervised translation approaches need parallel corpora as their data-set to learn the probability function of generating translation from source to target. We have solely utilized the WMT-20 Hindi-Marathi parallel corpus as the training data-set for the Attention Transformer model having 44,685 sentence pairs and used two human-level evaluation criteria, BLEU plus TER scores, to evaluate the Attention Transformer model. We have achieved BLEU points of 3.68 and a TER score of 97.64 for the Hindi-Marathi test pair. And, BLEU points of 9.02 with the TER score of 88.68 for the Marathi-Hindi test data-set. The future work under this domain includes applying stochastic optimizations like a genetic algorithm to find the best possible combinations of hyper-parameter to model the probability distribution of source to the target language. Furthermore, we can also stack a reinforcement learning paradigm on a developed supervised neural translation model to create a self-autonomous personalized environment for learning the probability function, which continuously gets updated by taking real-time feedback from the user.

Abstract

This paper reports the results for the Machine Translation (MT) system submitted by the NLPRL team for the Hindi – Marathi Similar Translation Task at WMT 2020. We apply the Transformer-based Neural Machine Translation (NMT) approach on both translation directions for this language pair. The trained model is evaluated on the corpus provided by shared task organizers, using BLEU, RIBES, and TER scores. There were a total of 23 systems submitted for Marathi to Hindi and 21 systems submitted for Hindi to Marathi in the shared task. Out of these, our submission ranked 6th and 9th, respectively.

1 Introduction

In the last decade and a half, neural machine translation (NMT) (Sutskever et al., 2014) has achieved great success in automatically translating human language text, outperforming statistical machine translation (SMT) (Koehn et al., 2003). Both the system require very large corpus sizes to train and evaluate the results. They, however, don't work very well for low resource data (He et al., 2016; Koehn and Knowles, 2017; Dowling et al., 2018). Translation from or to low resource languages is the major challenges faced by today's NMT systems.

Different methods have been proposed to overcome the data sparsity problem for low resource languages by researchers around the world. These include using monolingual data (Wu et al., 2019), fine-tuning (Miceli Barone et al., 2017) the high resource monolingual and parallel data on low resource data, back translation (Hoang et al., 2018), etc. They succeed up to some extent, but the success is limited, as the reported results show when compared to those for resource rich languages.

In this paper, we use the Transformer network-based NMT system (Vaswani et al., 2017) because it is among the state of the art models for machine translation. The work reported for this shared task is an extension of the work done by (Kumar and Singh, 2019) for similar languages task for 2019, which had also used a transformer based NMT system.

2 Similar Languages

Two languages are considered similar or closely related if they are close relatives in terms of the linguistic family of the linguistic family tree (or forest), or if the speakers of the two languages are in close contact over a long period of time. Contact over a long period leads to the exchange of cognates and loanwords between the speakers, sometimes even grammatical constructs.

Leveraging the close similarity of languages is one way to overcome the problem of data scarcity. Using similar features between such languages and improving translation is one of the directions for research for low resource machine translation.

For this submission, the motives behind conducting the shared task experiments are:

- To find out whether it is advantageous to use transformer-based NMT for similar languages.
- Whether using the SentencePiece [1] library without tokenization is beneficial for translation between similar languages or not.

3 Submitted System

We submitted two systems, namely, Marathi→Hindi and Hindi→Marathi. Both are the NMT systems trained on a Transformer (Vaswani et al., 2017) network. In this experiment, we did not tokenize data using any tokenizer. We directly applied SentencePiece library on the corpus. We found that directly applying

Parameters	Value
Encoder and decoder layers	5
Encoder embedding dimension	512
Decoder embedding dimension	512
Encoder attention heads	2
Decoder attention heads	2
Dropout	0.4
Attention dropout	0.2
Optimizer	Adam
Learning rate scheduler	inverse sqrt
Learning rate	1e-3
Minimum learning rate	1e-9
Adam-betas	(0.9, 0.98)
Number of epochs	100

Table 1: Hyperparameters used in our experiment

SentencePiece for preprocessing of data gives a better result. Since both the languages come under the category of morphologically rich and similar languages, directly applying SentencePiece on their corpus is advantageous. SentencePiece breaks the sentences into morphemes and phonemes. It extracts loanwords and cognate pairs. Breaking of sentences into subwords helps the neural translation network to learn better translations, and to generalize this knowledge to translate and produce unseen words, partly due to jointly developing the subword vocabulary.

4 Data

We trained the model on total 49434 number of Hindi - Marathi parallel corpus which belongs to three domains: News, PM India and Indic WordNet. Validation is done on total 1411 sentences. For testing, a total of 1941 sentences were used.

5 Experiment setup

We used fairseq [2] sequence to sequence encoder-decoder framework to train and evaluate the system. For hyper-parameter settings, we used the settings reported by (Guzmán et al., 2019) as these setting work well on low resource languages. Table 1 gives the hyper-parameter settings.

6 Results

Task organizers evaluate the systems using three evaluation metric: BLEU (Papineni et al., 2002), RIBES (Isozaki et al., 2010) and Translation Error Rate (TER) (Snover et al., 2006). We report the evaluation scores in table 2.

[2]https://github.com/pytorch/fairseq

system	BLEU	RIBES	TER
Marathi → Hindi	20.72	64.46	71.04
Hindi → Marathi	12.5	58.66	76.86

Table 2: Scores of our system evaluated by task organizers

7 Conclusion

In this paper, we perform experiments for translation between two similar languages: Hindi and Marathi. We submitted two systems: Marathi→Hindi and Hindi→Marathi, which were evaluated using BLEU, RIBES and TER. We found that SentencePiece works well for similar languages because it helps the Transformer in capturing the relations between two languages by providing morphemes, phonemes, cognate pairs, loanwords, etc. There were a total 23 systems submitted for Marathi → Hindi and 21 systems submitted for Hindi → Marathi in the shared task. Out of these, our system ranked 6th and 9th for Marathi → Hindi and Hindi → Marathi, respectively, considering the BLEU scores.

Abstract

Machine translation (MT) is a vital tool for aiding communication between linguistically separate groups of people. The neural machine translation (NMT) based approaches have gained widespread acceptance because of its outstanding performance. We have participated in WMT20 shared task of similar language translation on Hindi-Marathi pair. The main challenge of this task is by utilization of monolingual data and similarity features of similar language pair to overcome the limitation of available parallel data. In this work, we have implemented NMT based model that simultaneously learns bilingual embedding from both the source and target language pairs. Our model has achieved Hindi to Marathi bilingual evaluation understudy (BLEU) score of 11.59, rank-based intuitive bilingual evaluation score (RIBES) score of 57.76 and translation edit rate (TER) score of 79.07 and Marathi to Hindi BLEU score of 15.44, RIBES score of 61.13 and TER score of 75.96.

1 Introduction

MT is a well-known task of natural language processing (NLP) wherein automatic translation is performed between different languages. Broadly, MT is categorized into rule-based and corpus-based, where rule-based is based on a pre-defined rules on the concerned languages and corpus-based finds a generalized approach after being trained on a large corpus. MT switches from rule-based approach to the corpus-based which blots out the need for linguistic expertise. In the corpus-based approach, example-based machine translation (EBMT), statistical machine translation (SMT) and NMT techniques are available. The disadvantage of EBMT is that even though the corpus is large, all examples are not covered. To mitigate the issues of the contemporary approach SMT is introduced Brown et al. (1990); Koehn (2010). The SMT based system makes an assumption based on probability scores of the translated text. And hence, the ranking is done. SMT also faces many issues like system complexity, long term dependency problem, context-analyzing inability, word-alignment and the rare word problem. The inefficiency of SMT leads to the development of the NMT Devlin et al. (2014). But like SMT, the NMT based model also suffers the requirement of sufficient training parallel corpus, which is a challenge in the case of low resource languages. For this reason, there is a demand for direct translation among similar language pairs by utilizing similarity features and monolingual data, so that less availability of the parallel data does not pose a challenge. However, the NMT technique achieves state-of-the-art approach in MT because of its transformer model Vaswani et al. (2017). For low resource language pair translation, NMT models have been improved with monolingual corpus Sennrich et al. (2016b); Burlot and Yvon (2018); Wu et al. (2019). In this work, we have adopted cross-lingual language model (XLM) Conneau and Lample (2019) to implement an NMT model for Hindi-Marathi similar language translation task because XLM shows significant improvements for low-resource languages by utilizing the monolingual corpora.

2 Related Work

Hindi-Marathi translation lacks background work. However, similar work is found on Hindi-Nepali pair at WMT19 shared task of similar language translation Laskar et al. (2019). The literature survey mainly focuses on NMT for low resource language pairs since NMT outperforms conventional SMT on low resource pairs like English to Mizo, English to Hindi, English to Punjabi, and English to Tamil Pathak et al. (2018); Pathak and Pakray (2018); Laskar et al. (2019). It is noticed that train-

Proceedings of the 5th Conference on Machine Translation (WMT), pages 396–401

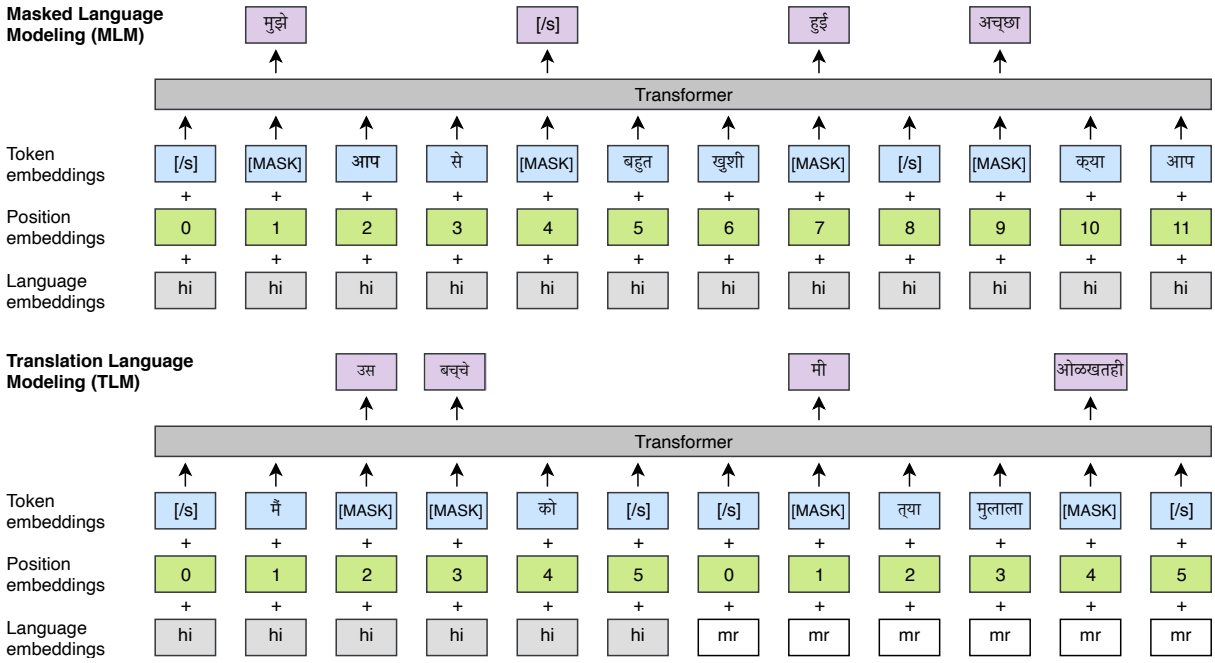

Figure 1: MLM pre-training inspired from Devlin et al. (2018) and TLM fine-tuning objective which extends the MLM task to parallel sentences as used by Conneau and Lample (2019). Diagram adapted from (Conneau and Lample, 2019) after suitable changes.

ing performance improves while parallel training data increases. For low resource languages, it is difficult to collect parallel data unlike monolingual data which is easily found through online sources. Hence, monolingual based NMT systems are introduced to enhance the translation quality of low resource language pair translation Sennrich et al. (2016b); Burlot and Yvon (2018); Wu et al. (2019). To get the advantage of monolingual data, unsupervised pre-train methods are introduced Ramachandran et al. (2017); Variš and Bojar (2019). Conneau and Lample (2019) proposed XLM based on bidirectional encoder representations from transformers (BERT) where the contextual language model is built with words based on preceding and succeeding context. No work has been done on Hindi-Marathi low resource language pair with such advanced NMT based approach, from the best of our knowledge. Our work investigates XLM model on Hindi-Marathi low resource language pair translation.

3 Dataset

3.1 Description

The organizers of WMT20 provided parallel and monolingual corpus for both Hindi and Marathi. The training dataset available for the WMT20, Hindi-Marathi task was obtained from three main sources viz. Indic WordNet, News, and PM India. Having 11,188, 12,349, and 25,897 parallel sentences (total 49434 sentences) respectively. The validation and test set contain 1941 and 1411 sentences. The Hindi monolingual dataset contains about 96 million sentences at about 32GB whereas the Marathi dataset is much smaller at only 4.72 million sentences totalling to around 2GB of corpus.

3.2 Preprocessing

We have removed unwanted symbols like URLs, email IDs and English text from the monolingual corpora of both the languages if any were to be present. In addition to this, since Hindi and Marathi languages share many common Devnagiri characters and hence to leverage this idea we have pre-processed the dataset obtained from Section 3.1 by a common vocabulary prepared via byte pair encoding (BPE) Sennrich et al. (2016a) on the same data provided by the organizer. Such an approach greatly helps in aligning the embedding space as shown in Lample et al. (2017). BPE learning is performed as used by Conneau and Lample (2019). The BPE is thus learnt after joining random sentences from the monolingual corpora. Following Conneau and Lample (2019) the text is sampled using a multinomial distribution. The distribu-

tion is as shown in Equation 1. The probabilities of the distribution are $p_{i=1...N}$. The BPE codes are generated and applied using the C++ implementation[1] of Sennrich et al. (2015).

$$p_i = \frac{q_i^\alpha}{\sum_{j=1}^{N} q_j^\alpha} \quad (1)$$

and p_i is as defined in Equation 2.

$$q_i = \frac{n_i}{\sum_{k=1}^{N} n_k} \quad (2)$$

α is taken as 0.5.

4 System Description

Our approach consists of the two principal approaches viz. the pre-training step and the fine-tuning step which are discussed in the following sub-sections 4.1 and 4.2. .

4.1 Pretraining our Model

For the pre-training step we have followed the steps of (Conneau and Lample, 2019) and utlized the masked language modeling (MLM) objective of (Devlin et al., 2018). Thus, following the work of Devlin et al. (2018) we have sampled 15% of BPE tokens randomly from the textual data and masked then by a `[MASK]` token roughly 80%. Also from the remaining 20%, the 10% component is randomly replaced and the rest part remains unchanged. The difference our approach has from the work of Devlin et al. (2018) is that, we have used lengths truncated to a fixed number (256 in our case), whereas the former uses pairs of sentences. To create a balance between the rare and commonly occuring BPE tokens like punctuation marks, the frequent outputs were subsampled using a multinomial distribution, where the weights are proportional to the inverse square root of the frequencies (an approach similar to Mikolov et al. (2013)). The pretraining objective is illustrated in Figure 1.

4.2 Fine Tuning

The model pre-training step follows an unsupervised approach and requires only the monolingual data. Since, the principal task for our work was to build a MT system, we need to leverage parallel data. Following, (Conneau and Lample, 2019) we used the translation language modeling (TLM) for fine-tuning the model obtained from Section 4.1. Here, instead of the truncated monolingual corpora we utlize the concatenation of parallel data as shown in Figure 1. Since the parallel sentences are concatenated for the concerned TLM task, we can mask and predict simultaneously from both Hindi and Marathi sentences. Enabling better placement of Hindi and Marathi word representations. Specifically as shown by Conneau and Lample (2019), this enables the model to leverage the context even if single handedly the source or target sentence is insufficient to decipher the sentence.

5 Experimental Setup

We have trained the transformer based cross language model (XLM) (Conneau and Lample, 2019) also known as MLM + TLM task. We have used 6 layers with 8 attention heads. An embedding layer is also used with size 256. Given the comparatively smaller Marathi dataset as discussed in Section 3.1, and limited availability of computational resources[2] we trained the smaller model instead of the usual 12 layers and 16 attention heads as proposed by Conneau and Lample (2019). Batch size of 32 was used. Following settings of Conneau and Lample (2019), attention dropout was set to 0.1, gelu activation was used. Also, adam was used as an optimizer with an initial learning rate of 0.0001. Rest of the parameters are same as used by Conneau and Lample (2019) in their experiments and as given in their GitHub repository[3].

6 Result and Analysis

The WMT20 organizer declared result for the shared task of similar language translation on Hindi to Marathi[4] and Marathi to Hindi[5] and the results of our system's is reported in Table 3. Our team's name is NITS-CNLP. The participated systems are evaluated by BLEU Papineni et al. (2002), RIBES Isozaki et al. (2010) and TER Snover et al. (2006) and the tracks are ranked by BLEU score. A total of 21 teams participated in Hindi to Marathi translation track and 23 teams for Marathi to Hindi translation track including both primary and contrastive system types. Our system's rank is 10 with BLEU score 11.59 for Hindi to Marathi translation

Table 2: Worst Performance examples for Hindi to Marathi translation.

Translation	System Type	BLEU	RIBES	TER
Hindi to Marathi	Primary	11.59	57.76	79.07
Marathi to Hindi	Primary	15.44	61.13	75.96

Table 3: Our system's results.

track and for Marathi to Hindi translation track, the rank is 15 with BLEU score 15.44 in primary configuration.

Analysis We have attained a lower BLEU score for Hindi to Marathi translation as compared to Marathi to Hindi translation as shown in Table 3. This is because we have used more Hindi monolingual corpus than Marathi monolingual corpus. As a result of this our NMT system encoded more frequency of Hindi words as compared to Marathi words and thus, decoder could be able to generate better target Hindi words than Marathi target words. To examine the best performance, we have considered sample source test sentences and corresponding predicted, Google[6], Bing[7] translated sentences for Hindi to Marathi translation in three different types of sentences such as short, medium and long sentences as shown in Table 1. Table 2 shows the worst performance of our NMT system in case of long type sentences. In Table 2, Google translation is better than our predicted test sentence and Bing translation.

7 Conclusion and Future Work

Our NMT system adopts cross lingual model for a similar language translation task of Hindi-Marathi pair in both forward and backward directions. The evaluated result and in-depth analysis of the predicted sentences shows that our NMT system performs well for the short and medium types of sentences and shows poor performance in long sentences. However, our NMT system needs more Marathi monolingual corpus and in the future works, multilingual NMT system will be developed to overcome the limitation of corpus for such low resource language pair translation.

Transfer Learning for Related Languages: Submissions to the WMT20 Similar Language Translation Task

Lovish Madaan, Soumya Sharma, Parag Singla
Indian Institute of Technology, Delhi
{lovish97, soumyasharma98}@gmail.com, parags@cse.iitd.ac.in

Abstract

In this paper, we describe IIT Delhi's submissions to the WMT 2020 task on Similar Language Translation for four language directions: Hindi ↔ Marathi and Spanish ↔ Portuguese. We try out three different model settings for the translation task and select our primary and contrastive submissions on the basis of performance of these three models. For our best submissions, we fine-tune the mBART model (Liu et al., 2020) on the parallel data provided for the task. The pre-training is done using self-supervised objectives on a large amount of monolingual data for many languages. Overall, our models are ranked in the top four of all systems for the submitted language pairs, with first rank in Spanish → Portuguese.

1 Introduction

Machine Translation (MT) is currently tackled using rule-based methods (RBMT) (Charoenpornsawat et al., 2002), phrase-based statistical methods (SMT) (Koehn et al., 2003) and neural methods (NMT) (Cho et al., 2014; Sutskever et al., 2014; Bahdanau et al., 2015; Vaswani et al., 2017).

NMT has achieved high translation quality for several language pairs (Bojar et al., 2018; Barrault et al., 2019), but this level of performance usually requires large amounts of aligned data in the order of millions of sentence pairs. For low and medium resource languages, SMT performs better than NMT (Koehn and Knowles, 2017; Sennrich and Zhang, 2019). SMT also shows better performance when there is a domain mismatch between the train and test datasets, which is typical of low and medium resource language pairs.

In these settings, NMT performance can be boosted by leveraging additional monolingual data to enforce various types of constraints or increasing the training data using back-translation. These methods can be particularly helpful if the source and target languages in MT are closely related and share language structure and alphabet. Recently, pre-training methods for sequence-to-sequence (seq2seq) models have been introduced like MASS (Song et al., 2019a), XLM (Conneau and Lample, 2019), BART (Lewis et al., 2019), and mBART (Liu et al., 2020). These methods show significant gains in downstream tasks like NMT, summarization, natural language inference (NLI), etc. In this paper, we focus on the transfer learning capabilities in NMT for the task of translation between related languages where parallel data is scarce.

IIT Delhi participated in the WMT 2020 Shared task on Similar Language Translation for four language directions: `Hindi (hi)` ↔ `Marathi (mr)` and `Spanish (es)` ↔ `Portuguese (pt)`. The first language pair is low resource and second is medium resource in terms of the parallel data available for the task. Refer to Table 2 for the classification.

We fine-tuned the pre-trained mBART model (Liu et al., 2020) on the parallel data provided for the task. mBART gives better performance than SMT models even when the parallel data is very limited. mBART is pre-trained on 25 languages, which contain Hindi and Spanish, but not Marathi and Portuguese. mBART is able to leverage transfer learning capabilities even for those languages that are originally not present during the pre-training phase. The fine-tuned mBART architecture forms our best submissions for both language pairs: `hi` ↔ `mr` and `es` ↔ `pt`. The rankings obtained by us in each of the language directions are listed in Table 1. Our findings are in line with earlier observations in the literature where transfer learning techniques have been shown to significantly boost NMT performance.

The rest of the paper is organized as follows: Section 2 provides the background and related work for low/medium resource NMT. Section 3 gives an

overview of the systems tried. In Section 4, we present the experiments and training pipeline setup. The results and analysis are detailed in Section 5. We finally conclude in Section 6.

2 Background

SMT is tackled by building a phrase table from the aligned parallel data. The target side translation is then generated by matching the most appropriate phrases in the source sentence conditioned on the target side language model along with a reordering model (Koehn et al., 2003).

NMT is modeled using Encoder-Decoder models (Cho et al., 2014; Sutskever et al., 2014; Bahdanau et al., 2015), with the Transformer model (Vaswani et al., 2017) achieving state-of-the-art on many MT problems. But these models' reliance on large aligned parallel data for the source and target languages makes them unsuitable for low/medium resource language pairs (Koehn and Knowles, 2017). Some of the previous works in these settings to improve NMT performance are described below:

2.1 Multilingual NMT

Instead of using only two languages (source and target) for training an NMT model, using multiple languages has been shown to help in low resource scenarios. For example, it might be the case that a certain pair of languages have very little parallel data between them, but there exists a third language with abundant parallel data with the original two languages. This third language acts as a pivot and helps in improving NMT between the two languages (Aharoni et al., 2019; Gu et al., 2018; Liu et al., 2020; Zhang et al., 2020).

2.2 Back-Translation

Back-Translation (Sennrich et al., 2016; Edunov et al., 2018; Hoang et al., 2018) increases the amount of training data by using monolingual corpus along with partially-trained NMT models on the limited parallel data. Pseudo-parallel corpus for each direction is first obtained by generating the translations of the monolingual data for each language using the partially-trained MT models on the limited parallel data. Using these pseudo-parallel corpora, the partially-trained NMT models are then trained further for some number of steps. In this way, millions of pseudo-parallel sentence pairs can be generated to improve NMT models because of the abundance of monolingual data. Another version of using back-translation is the copying mechanism. Currey et al. (2017) proposes to copy the target side monolingual data on the source side to create additional data without modifying the training regimen for NMT. This helps the model to generate fluent translations.

2.3 Pre-trained Language Models

For NMT, the first step is the random initialization of model weights in both the encoder and decoder. Instead of random initialization, NMT models can be initialized by pre-training parts of the model (Conneau and Lample, 2019; Edunov et al., 2019), or pre-training the complete seq2seq model (Ramachandran et al., 2017; Song et al., 2019b; Liu et al., 2020). These pre-training methods leverage different kinds of masking techniques and the pre-training objective is to predict these masked tokens, similar to BERT (Devlin et al., 2019). Denoising auto-encoding can also be used where a sentence is corrupted by various noising techniques and the pre-training objective is to generate the original uncorrupted sentence as in BART (Lewis et al., 2019) and mBART (Liu et al., 2020).

2.4 Incorporating Linguistic Information in NMT

There also have been works to improve low/medium resource NMT by adding linguistic information either using data augmentation (Currey and Heafield, 2019), subword embedding augmentation (Sennrich and Haddow, 2016) , or architectural changes (Eriguchi et al., 2017). This helps the model to not only learn the alignment between source and target language spaces, but also syntax structure like dependency parse, part of speech, etc. This helps in making the target side translations more fluent and conforming to the structure of the language. We do not explore this direction in this paper.

3 System Overview

We experimented with three different settings for hi ↔ mr as listed below.

SMT This phrase-based system leverages both monolingual and parallel data provided for the task. We use Moses (Koehn et al., 2007) for training the SMT systems.

NMT (Transformer) For this, we used the standard Transformer large architecture from Vaswani et al. (2017) for training on the parallel data provided for the task.

NMT (mBART) mBART (Liu et al., 2020) is a large Transformer pre-trained on monolingual data for 25 languages. The pre-training objective for mBART is seq2seq de-noising for natural text as in BART (Lewis et al., 2019). mBART provides a general-purpose pre-trained Transformer for any downstream task. It has been shown to give significant improvements over the random initialization for NMT and is the current state-of-the-art for many low resource language pairs.

Implementation Details mBART uses a shared subword vocabulary of 250K tokens for all the 25 languages present in the pre-training. We use the same vocabulary for Marathi and Portuguese also, even though they were not used during the pre-training phase. Marathi shares its subword vocabulary with languages like Hindi and Nepali in mBART, and Portuguese shares with Spanish, Italian and other European languages present in mBART. The percentage of unknown tokens [UNK] in Marathi and Portuguese parallel datasets is less than 0.003% when using the shared mBART vocabulary.

Additionally, the mBART architecture requires language specific token at the end of each input sequence to provide the language specific context for the decoder. Since Marathi and Portuguese were not present during the pre-training phase, we use the token corresponding to the second most related language present in mBART pre-training for specifying the context at the time of decoding in each case. For Marathi, we used the Nepali language token and for Portuguese, we used the Italian language token. We could not use Spanish language token for Portuguese because we are doing translations to and from Spanish.

	train	valid	test
hi ↔ mr	43,274	1,411	1,941
es ↔ pt	3,472,860	1,283	1,495

Model	**hi - mr**	
	←	→
SMT	18.74	14.91
mBART	**24.53**	**15.14**

Table 3: BLEU scores on Hindi ↔ Marathi on the test set for our primary and contrastive submissions.

4 Experiments

We use hi ↔ mr and es ↔ pt language pairs for our experiments.

4.1 Datasets & Preprocessing

Because of the constrained nature of the shared task, we only use the parallel data provided for this task. We removed the empty instances for both language pairs (< 2000 instances). For es ↔ pt, we do not use 'WikiTitles v2' part of the parallel data for training because of very short sentences in the dataset. The cleaned parallel dataset statistics are provided in Table 2.

Preprocessing We use sentence piece tokenization (Kudo and Richardson, 2018) for generating the source and target sequences for the NMT architectures. For the standard Transformer, we train a sentence piece model using 40K subword tokens for hi ↔ mr. For mBART, we use Liu et al. (2020)'s pre-trained[1] sentence piece model comprising of 250K subword tokens as the vocabulary.

For the SMT model on hi ↔ mr, we also use the monolingual data provided for this task. We extract 5 Million monolingual sentences each for Hindi and Marathi after deduplication and use this set for training the language models. We use Moses (Koehn et al., 2007) for all tokenization / detokenization scripts.

IIT Delhi (ours)	**24.53**	15.14	32.84	**32.69**
Rank 1	24.53	18.26	33.82	32.69

Table 4: Hindi - Marathi and Spanish - Portuguese BLEU scores on the test dataset of the Similar Language Translation Task. Our submission scores are bolded when they match the first ranked submission.

4.2 Model Architectures & Training

SMT We generate a phrase table for the SMT model using the code provided by Lample et al. (2018). We used Moses (Koehn et al., 2007) and Giza++ with standard settings to train the SMT model in both directions.

NMT (Transformer) We use the large Transformer from Vaswani et al. (2017) with 8 encoder and decoder layers and replicate all the parameters from Ott et al. (2018). The number of parameters in the model are approximately 248 Million and it takes ∼26 hours on 4 Nvidia V100 (32 GB) GPUs.

NMT (mBART) For this, we use 12 Transformer encoder and decoder layers, with total number of model parameters ∼611 Million. We use the pre-trained mBART for initializing the model weights. We follow the recommendations of Liu et al. (2020) for the hyperparameter settings. We stop the training after 25K gradient updates for the model. These updates take ∼35 hours on 4 Nvidia V100 (32 GB) GPUs.

4.3 Evaluation

We use case-insensitive BLEU scores (Papineni et al., 2002) calculated using sacreBLEU[2] (Post, 2018). These scores are calculated on the validation set to decide our primary and contrastive submissions. For evaluating performance on the test set, the organizers use BLEU, TER (Snover et al., 2006), and RIBES (Isozaki et al., 2010).

5 Results and Analysis

Results Table 3 shows our results on the test set for our primary and contrastive submissions. We observed the performance of our three model settings on the validation set, and we selected the mBART model as our primary submission and SMT model as the contrastive submission for `hi` ↔ `mr`. Similarly, the mBART model forms our primary submission for `es` ↔ `pt`. Table 4 lists our final results on this shared task. We also list the BLEU scores for the submission that got first rank in each of the language directions. Since the test sets were hidden at the time of submission, we do not report our numbers on the standard Transformer architecture.

Analysis Even though Marathi and Portuguese are not present during the pre-training phase of mBART, fine-tuning on these languages provides significant boosts over SMT and standard Transformer. This shows that some level of language independent multilingual embeddings are present in the pre-trained model weights which can be exploited for the transfer task.

6 Discussion and Conclusion

We have participated in the Similar Language Translation task on four language directions. We have shown that pre-trained models can help in low and medium resource NMT. Our best system uses the pre-trained mBART model (Liu et al., 2020) and fine-tunes on the parallel data provided for the specific translation task. Our results demonstrate that pre-training can help even when the language used for fine-tuning is not present during pre-training.

One direction of future work is to add linguistic information during the pre-training phase to get more fluent translations. When this information is not available directly (especially for low resource languages), pre-training on a related high resource language with syntax information can help low resource languages also.

Acknowledgments

We thank the IIT Delhi HPC facility[3] for the computational resources. We are also thankful to Ganesh Ramakrishnan and Pawan Goyal for initial discussions on the project. Parag Singla is supported

Abstract

This paper describes the participation of the NLP research team of the IPN Computer Research center in the WMT 2020 Similar Language Translation Task. We have submitted systems for the Spanish-Portuguese language pair (in both directions). The three submitted systems are based on the Transformer architecture and used fine tuning for domain Adaptation.

1 Introduction

In this paper we describe the Neural Machine Translation(NMT) systems developed by the NLP team of the Computer Research System of the Instituto Politécnico Nacional, México for the similar languages translation shared task of the EMNLP 2020 fifth conference on machine translation (WMT 20).

For this task, we submit systems for both directions of the Spanish-Portuguese language pair, all the submitted systems were based in a transformer architecture with a fine tuning for domain adaptation, the difference of the submitted systems was mainly the kind of tokens used (words and sub-word units) and the initialization of the word embeddings in the systems using either a random initialization or pre-trained word embeddings.

In the past year task, the submissions of the MLLP-UPV team (Baquero-Arnal et al., 2019) showed that the use of fine tuning was proven to be useful in this specific task, although the test corpus of this year had a higher complexity, the use of fine tuning for context adaptation was also beneficial for translation quality.

The paper was organized in the following way. Section 2 describes the architecture used for the systems trained, the section 3 describes the corpora used and the pre-processing of the texts, the section 4 gives a description of the training of the system, section 5 gives a description of the method used for obtaining the translations from the trained system, section 6 shows the results for both the internal evaluation and the evaluation of the task, section 7 is a discussion about the impact of pre-trained word embeddings in the submitted systems and section 8 presents the conclusions.

1.1 Transformer models in NMT

Before transformers most state-of-the-art MT systems relied on recurrent neural networks, with attention mechanisms, but the RNN based architectures although that in theory the information of each token can propagate arbitrary far down in the sequence, due to vanishing gradient in practice when dealing with long sentences or sequences information about the initial tokens can be lost.

As a solution of that problem transformers (Vaswani et al., 2017) are an architecture based in an encoder -decoder approach, but rely mainly in self attention mechanisms.

1.1.1 Encoder

Each encoder layer consists of two components: a self-attention mechanism and a feed-forward neural network. The self-attention mechanism receives a set of encoded representation from the previous layer and weights it in order to generate a set of output encodings. The feed forward network processes each output encoding and passes it to the next encoder and to the decoders.

The first encoder layer uses as arguments positional information and the word embeddings, instead of encodings.

1.1.2 Decoder

Each decoder layer has three main components: A self-attention mechanism, an over the encodings attention mechanism and a feed-forward network. The decoder layer works in a similar way than a encoder one, but the additional attention mecha-

Proceedings of the 5th Conference on Machine Translation (WMT), pages 409–413

nism uses the relevant information produced by the encoder layers.

In a similar structure from the first encoder layer, the first decoder layer also receives as inputs positional information and the embeddings of the output sequence. Due to the transformer should not know current or future information in order to predict the next word, the output sequence should be partially hidden during the training of the system.

The last decoder layer is followed by a linear transformation and a softmax layer to produce the probability of the words in the vocabulary.

1.2 Word embeddings initialization

Word embeddings are a solution in Natural Language Processing for the problem of having spare word spaces of high dimensionality that happens with the one-hot vectors representation.

Word embeddings uses a machine learning algorithm in order to learn the relations between words and contexts from big corpora, proposed from (Mikolov et al., 2013)

Inside of neural networks architecture approaches, word embeddings are generally used as a word representation in both source and target languages which are usually random initialized, but it is also possible to use pre-trained word embeddings and updated it in the training time.

Fast text (Bojanowski et al., 2016) is a library used to learn word embeddings, this model aims to create supervised and non-supervised systems to obtain word representation. It is also provided by the project pre-trained embeddings for 294 languages.

In the current paper an approach using fast-text vectors for the initialization of a transformer model is attempted, using the pre trained vectors in both Spanish and Portuguese languages.

2 Architecture of the submission

The main model for the submission consisted in a transformer model that used tokens composed by words and the word embeddings inside the transformer architecture were initialized using pre trained fast text embeddings in both, source and target languages.

For contrastive purposes two additional models were added to the submission , neither of them used a special initialization of the word embeddings and the main distinction between them was the kind of tokens used in the training, the first one used words and the later used sub word units gated by a BPE algorithm.

Corpus	Version	Sentences
JCR	1	1,650,126
Europarl	10	1,801,845
News commentary	15	48,259
Wikititles	2	649,833

Table 1: Training corpora

2.1 Model description

The three models for the submission differs in the following way:

1. **Primary:** Model that was initialized using pre trained fast-text word embeddings, and tokens constituted by words

2. **Contrastive1:** Model that was initialized with random word embeddings. Used tokens formed by words

3. **Contrastive2:** Model that was initialized with random word embeddings. Used tokens formed by BPE sub-word units

Where the primary model was the main model for the submission and the contrastive models serves as baselines.

For the comparative between the three models, BLEU (Papineni et al., 2002) was computed with the `Sacrebleu` (Post, 2018).

2.2 Transformer model

For the transformer model the configuration used consists of a model size of 6 layers, 512 feed-forward size, 8 heads, trained on one GPU with a batch size of 4096 tokens using. We stored a checkpoint every 5000 steps until 200000.

We used Adam optimizer with a β 2 of 0.998 The models were built using Open NMT toolkit (Klein et al., 2017).

3 Corpus description

The training data was made up with the available training data for the task, that is JCR, Europarl, news commentary and wikititles corpora. The provided development set was randomly split in two disjoint sets of the same size, dev1 and dev2 sets.

The data was prepossessed using the following pipeline tokenization, lowercasing and a BPE algorithm learned over the test set.

Model	Before	After
Primary	24.20	32.56
Contrastive1	23.94	30.43
Contrastive2	24.49	30.2

Table 2: BLEU for the models before and after fine-tuning for ES-PT

Model	Before	After
Primary	27.61	34.41
Contrastive1	27.21	34.11
Contrastive2	27.26	34.18

Table 3: BLEU for the models before and after fine-tuning for PT-ES

4 Training

The training for all the systems was carried in a two steps way.

In the first step the model was trained using the training set during 200 thousand steps, storing a checkpoint every 5000 steps. For all the checkpoint generated, a translation of the dev-set was computed and BLEU evaluated against a tokenized and lowercased version of the dev1 set.

Due to the conformation of the training data, that is made mostly of parlament sesions (Europarl) and scientific journals (JCR) and the observation that this domains doesn't appear in the test data there is an assumption of a domain mismatch between training and test data. Due to this mismatch in the second step a fine tunning of the model is conducted.

This fine tuning was trained from the best BLEU scored checkpoint and a retraining was made using the dev1 set up to 3000 steps, storing a checkpoint every 10. For all the stored checkpoints, a translation of the test set was computed and evaluated with BLEU against a tokenized and lowercased version of the dev2 set.

For the generation of the translations for the submission the checkpoint with the best BLEU score in the fine tuning step was used.

5 Translations generation

In order to get the translation for the evaluation the `translate.py` script of Open NMT was used with a beam of size 5 and a length penalization with alpha of 5.

After getting the translations the texts was passed through a recaser trained over the training corpora using the script `recaser.perl` from Moses, after this step a detokenizer was used.

6 Results

The tables 2 and 3 shows the BLEU obtained in the evaluation of the three different models before and after the fine tuning for the ES-PT and PT-ES language pairs respectively.

Model	BLEU	RIBES	TER
Primary	27.08	72.98	55.34
Contrastive1	23.91	71.55	57.55
Contrastive2	23.9	73.73	58.07

Table 4: Official results for submitted ES-PT systems

In this internal evaluation of the models the primary model outperforms the baseline models by 2.7 BLEU points for ES-PT direction and 0.18 points in PT-ES.

6.1 Task results

The evaluation of the task was carried using BLEU, RIBES (Isozaki et al., 2010) and TER (Snover et al., 2006) metrics the main difference between this measure and the internal one was that the internal evaluation used a tokenized lowercased version of the text and the task results used the final version.

The tables 4 and 5 show the results of the submitted systems in the task evaluation for the ES-PT and PT-ES language pairs respectively.

In this evaluation again the primary model outperforms the baseline models by a margin of 3 and 0.4 BLEU points for the ES-PT and PT-ES directions respectively.

7 Impact of the pre trained word embeddings

The pre-trained word embeddings used for the model were filtered in order to include only the words that was present in either the development set or the test set and preprocessed using the script `embeddings_to_torch.py` included in the Open NMT toolset.

The used word embeddings showed an im-

Model	BLEU	RIBES	TER
Primary	28.38	72.24	56.27
Contrastive1	27.98	72.11	56.16
Contrastive2	27.41	75.18	57.28

Table 5: Official results for submitted PT-ES systems

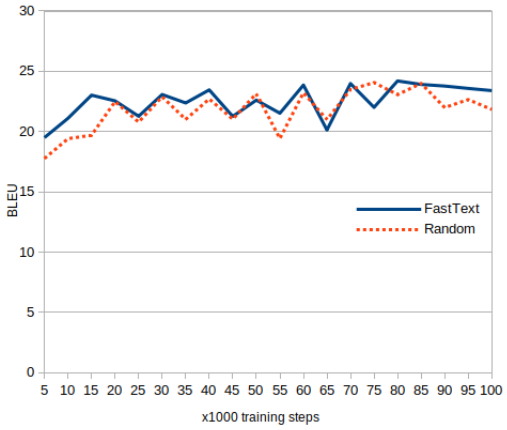

Figure 1: Training for ES - PT

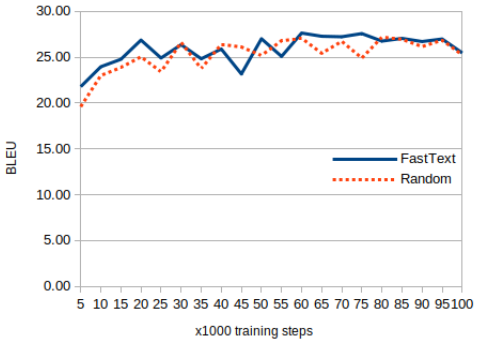

Figure 2: Training for PT - ES

provement in the translation quality (according to BLEU).

Figures 1 and 2 show comparatives for the ES-PT and PT-ES directions respectively for the first 100k training steps for the model 1 and 3, that means comparing both systems trained in words with the unique difference is that system 1 has fast text pre-trained word embeddings.

From the comparative in figures 1 and 2 we can extract that the use of pre-trained word embbedings was beneficial in the beginning of the training, with a difference of around 2 BLEU points in the first 5000 training steps for both ES-PT and PT-ES directions.

Similar results were seen in the fine tuning of the systems, in this case due to the short amounts of epoch for the training of this step a more detailed table is not provided, but in the tables 2 and 3 a difference of 2.7 and 0.3 BLEU points can be seen for the ES-PT and PT-ES directions respectively.

8 Conclusions

The initialization using fast text had a beneficial result in this low resource scenario, but the embeddings used were trained in a general context, is possible that pre-trained the embeddings in the specific context could gather better results.

In this specific experiment both contrastive models had similar results, independently of the kind of tokens used during the training.

Compared with the 2019 edition of the SLT task, this year the test corpus had a different domain, resulting in a lower BLEU score using similar techniques, but also in this year the use of fine tuning improved the translation margin in around 9 points for ES-PT and in almost 7 points for the evaluation using the development set in the primary models.

For the next year submission, the use of word embeddings can be expanded using word embeddings trained in a bilingual context or in a similar domain from the one in the test corpora.

Abstract

This paper describes the participation of team F1toF6 (LTRC, IIIT-Hyderabad) for the WMT 2020 task, similar language translation. We experimented with attention based recurrent neural network architecture (seq2seq) for this task. We explored the use of different linguistic features like POS and Morph along with back translation for Hindi-Marathi and Marathi-Hindi machine translation.

1 Introduction

Machine Translation (MT) is the field of Natural Language Processing which aims to translate a text from one natural language (i.e Hindi) to another (i.e Marathi). The meaning of the resulting translated text must be fully preserved as the source text in the target language.

For the translation task, different types of machine translation systems have been developed and they are mainly Rule based Machine Translation (RBMT)(Forcada et al., 2011), Statistical Machine Translation (SMT) (Koehn, 2009) and Neural Machine Translation (NMT) (Bahdanau et al., 2014).

Statistical Machine Translation (SMT) aims to learn a statistical model to determine the correspondence between a word from the source language and a word from the target language. Neural Machine Translation is an end to end approach for automatic machine translation without heavily hand crafted feature engineering. Due to recent advances, NMT has been receiving heavy attention and achieved state of the art performance in the task of language translation. With this work, we intend to check how NMT systems could be used for low resource and similar language machine translation.

Data	Sents	Token	Type
Hindi (Parallel)	38,246	7.6M	39K
Marathi (Parallel)	38,246	5.6M	66K
Hindi (Mono)	80M	-	-
Marathi (Mono)	3.2M	-	-

Table 1: Hindi-Marathi WMT2020 Training data

This paper describes our experiments for the task of similar language translation of WMT-2020. We focused only on Hindi-Marathi language pair for the translation task (both directions). The origin of these two languages are the same as they are Indo-aryan languages(wikipedia, 2020). Hindi is said to have evolved from Sauraseni Prakrit (wikipedia Hindi, 2020) whereas Marathi is said to have evolved from Maharashtri Prakrit (wikipedia Marathi, 2020). They also have evolved as two major languages in different regions of India.

In this work, we focused only on recurrent neural network with attention based sequence to sequence architecture throughout all experiments. Along with it, we also explored the morph(Virpioja et al., 2013) induced sub-word segmentation with byte pair encoding (BPE)(Sennrich et al., 2016b) to enable open vocabulary translation. We used POS tags as linguistic feature and back translation to leverage synthetic data for machine translation task in both directions. In the similar language translation task of WMT-2020, we participated as team named “f1plusf6”.

2 Data

We utilised parallel and monolingual corpora provided for the task on Hindi<->Marathi language pairs. Table-1 describes the training data (parallel

Proceedings of the 5th Conference on Machine Translation (WMT), pages 414–417

and monolingual) on which we carried out all experiments. We deliberately excluded Indic WordNet data from the training after doing manual quality check. As this is a constrained task, our experiments do not utilise any other available data.

3 Pre-Processing

As a first pre-precessing step we use IndicNLP Toolkit[1] along with an in-house tokenizer to tokenize and clean both Hindi and Marathi corpora (train, test, dev and monolingual).

3.1 Morph + BPE Segmentation

Marathi and Hindi are morphologically rich languages and from the Table-1, based on the the comparative token/type ratio, one can find that Marathi is a more agglutinative language than Hindi. Translating from morphologically-rich agglutinative languages is more difficult due to their complex morphology and large vocabulary. To address this issue, we have come up with a segmentation method which is based on morph and BPE segmentation (Sennrich et al., 2016b) as a pre-processing step.

In this method, we utilised unsupervised Morfessor (Virpioja et al., 2013) to train a Morfessor model on monolingual data for both languages. We then applied this trained Morfessor model on our corpora (train, test, validation) to get meaningful stem, morpheme, suffix segmented sub-tokens for each word in each sentence.

(1) aur jab maansaahaaree
pakshee lothon par jhapate ,
tab abraam ne unhen uda diya .
'And when the carnivorous birds swooped on the carcasses, Abram blew them away.'

(2) aur jab maansaa##haaree
pakshee loth##on par jhapat##e ,
tab ab##raam ne unhen uda diya .
'And when the carnivorous birds swooped on the carcasses, Abram blew them away.'

(3) aur jab maan@@ saa##haaree
pakshee loth##on par jha@@ pat##e ,
tab ab##raam ne unhen uda diya .
'And when the carnivorous birds swooped on the carcasses, Abram blew them away.'

We demonstrate this method with a Hindi sentence as given in Example-1. Example -1, shows Hindi text with romanized text and the corresponding English translation for better understanding. The Example-2 shows the same sentence with Morfessor based segmentation with token ##. Here we notice that Morfessor model has segmented the Hindi words into meaningful stems and suffixes. i.e maansaahaaree=maansaa + haaree(meat + who eats). We would like to use it in our experiments to tackle the difficulties that arise due to complex morphology at the source language in machine translation tasks. On top of this morph segmented text we applied BPE (Sennrich et al., 2016a) as given in Example-3. Here @@ is sub-word separator for byte pair based segmentation and ## is the separator for morph based segmentation.

3.2 Features

For Hindi to Marathi translation, we carried out experiments using Part of Speech (POS) tags as a word level as well as a subword level feature as described in (Sennrich and Haddow, 2016). We use LTRC shallow parser[2] toolkit to get POS tags.

4 Training Configuration

Recurrent Neural Network (RNN) based machine translation models work on encoder-decoder based architecture. Here, the encoder takes the input (source sentence) and encodes it into a single vector (called as a context vector). Then the decoder takes this context vector to generate an output sequence (target sentence) by generating a word at a time(Sutskever et al., 2014). Attention mechanism is an extension to this sequence to sequence architecture to avoid attempting to learn a single vector. Instead, based on learnt attention weights, it focuses more on specific words at the source end and generates a word at a time. More details can be found here (Bahdanau et al., 2014), (Luong et al., 2015).

For our experiments, we utilize sequence to sequence NMT model with attention for all of our experiments with following configuration.

BiLSTM + LuongAttn	BPE+SV+MORPH+POS	20K	**25.55**
BiLSTM + LuongAttn	BPE+SV+MORPH+POS + BT	20K	23.80

Table 3: BLEU scores on Development data for Marathi-Hindi

- Morph + BPE based subword segmentation, POS tags as feature
- Embedding size : 500
- RNN for encoder and decoder: bi-LSTM
- Bi-LSTM dimension : 500
- encoder - decoder layers : 2
- Attention : luong (general)
- copy attention(Gu et al., 2016) on dynamically generated dictionary
- label smoothing : 1.0
- dropout : 0.30
- Optimizer : Adam
- Beam size : 4 (train) and 10 (test)

As these are two similar languages, share writing scripts and large sets of named entities, we used shared vocab across training. We used Opennmt-py (Klein et al., 2020) toolkit with above configuration for our experiments.

5 Back Translation

Back translation is a widely used data augmentation method for low resource neural machine translation(Sennrich et al., 2016a). We utilised monolingual data (i.e of Marathi) and a NMT model trained on given training data for a direction (i.e, Marathi to Hindi) to enrich training data of the opposite directional NMT training (i.e, Hindi - Marathi) by populating synthetic data. We used around 5M back translated pairs (after perplexity based pruning with respect to sentence length) for both translation directions.

Using above described configuration, we performed experiments based on different parameter (feature) configurations. We trained and tested our models on word level, BPE level and morph + BPE level for input and output. We also used POS tagger and experimented with shared vocabulary across the translation task. The results are discussed in following Result section.

6 Result

Table-2 and Table-3 show performance of systems with different configuration in terms of BLEU score(Papineni et al., 2002) for Hindi-Marathi and Marathi-Hindi respectively on the validation data. We achieved 20.62 and 25.55 development and 5.94 and 18.14 test BLEU scores for Hindi-Marathi and Marathi-Hindi systems respectively.

The results show that for low resource similar language settings, MT models based on sequence to sequence neural network can be improved with linguistic information like morph based segmentation and POS features. The results also show that morph based segmentation along with

byte pair encoding improves BLEU score for both directions. But Marathi-Hindi directed translation shows considerable improvement. Therefore our method shows improvement while translating from morphologically richer language (Marathi) to comparatively less morphologically richer language (Hindi).

The results also suggest that the use of back translated synthetic data for low resource language pairs reduces the overall performance marginally. The reason for this could be, due to low quantity of training data for NMT models, they could be over learning and back translation could be helping to do better generalization.

7 Conclusion

We conclude from our experiments that linguistic feature driven NMT for similar low resource languages is a promising approach. We also believe that morph+BPE based segmentation is a potential segmentation method for morphologically richer languages.

Abstract

NUIG-Panlingua-KMI submission to WMT 2020 seeks to push the state-of-the-art in the Similar language translation task for the Hindi ↔ Marathi language pair. As part of these efforts, we conducted a series of experiments to address the challenges for translation between similar languages. Among the 4 MT systems prepared for this task, 1 PBSMT systems were prepared for Hindi ↔ Marathi each and 1 NMT systems were developed for Hindi ↔ Marathi using Byte Pair Encoding (BPE) of subwords. The results show that different architectures in NMT could be an effective method for developing MT systems for closely related languages. Our Hindi-Marathi NMT system was ranked 8th among the 14 teams that participated and our Marathi-Hindi NMT system was ranked 8th among the 11 teams participated for the task.

1 Introduction

Developing automated relations between closely related languages is a contemporary concern especially in the domain of Machine Translation(MT). Hindi and Marathi exhibit a significant overlap in their vocabularies and strong syntactic plus lexical similarities. These striking similarities seem promising in enhancing the possibility of mutual inter-comprehension within closely related languages. However, automated translation between such closely related languages is a rather challenging task.

The linguistic similarities and regularities in morphological variations and orthography motivate the use of character-level translation models, which have been applied to translation (Vilar et al., 2007; Chakravarthi et al., 2020) and transliteration (Matthews, 2007; Chakravarthi et al., 2019a; Chakravarthi, 2020). In the past few years, neural machine translation systems have achieved outstanding performance with high resource languages, with the help of open source toolkit such as OpenNMT (Klein et al., 2017), Marian (Junczys-Dowmunt et al., 2018) and Neamtus (Sennrich et al., 2017), which provide various ways of experimenting with the use of different features and architectures, yet it fails to achieve the same results with low resource languages (Chakravarthi et al., 2018, 2019b). However, Sennrich and Zhang (2019) revisited the NMT models and tuned hyper-parameters, changed network architectures to optimize NMT for low-resource conditions and concluded that low-resource NMT is very sensitive to hyper-parameters such as Byte Pair Encoding (BPE) vocabulary size, word dropout, and others. This paper is an extension of our work Ojha et al. (2019) submitted to WMT 2019 similar language translation task. Therefore our team adapted methods of the low resource setting for NMT proposed by Sennrich and Zhang (2019) to explore the following broad objectives:

- to compare the performance of SMT and NMT in case of closely related, relatively low-resourced language pairs, and
- to findout how to leverage the accuracy of NMT in closely related languages using BPE into subwords.
- to analyze the effects of data quality in performance of the systems.

2 System Description

This section provides an overview of the systems developed for the WMT 2020 Shared Task. In these experiments, the NUIG-Panlingua-KMI team explored two different approaches: phrase-based statistical (Koehn et al., 2003), and neural method for Hindi-Marathi and Marathi-Hindi language pairs. In all the submitted systems, we use the Moses (Koehn et al., 2007) and Nematus (Sennrich et al., 2017) toolkit for developing statistical and neural

Proceedings of the 5th Conference on Machine Translation (WMT), pages 418–423
Online, November 19–20, 2020.

machine translation systems respectively. The pre-processing was done to handle noise in data (for example, different language sentences, non-UTF characters etc), the details of which are provided in section 3.1

2.1 Phrase-based SMT Systems

These systems were built on the Moses open source toolkit using the KenLM (Heafield, 2011) language model and GIZA++ (Och and Ney, 2003) aligner. 'Grow-diag-final-and heuristic' parameters were used to extract phrases from the corresponding parallel corpora. In addition to this, KenLM was used to build 5-gram language models.

2.2 Neural Machine Translation System

Nematus was used to build 2 NMT systems. As we mentioned in an earlier section, at first data was pre-processed at subwords level with BPE for neural translation, and then the system was trained using Nematus toolkit. Most of the system features were adopted from (Sennrich et al., 2017; Koehn and Knowles, 2017) (see section 3.3.2).

2.3 Assessment

Assessment of these systems was done on the standard automatic evaluation metrics: BLEU (Papineni et al., 2002), Rank-based Intuitive Bilingual Evaluation Score (RIBES) (Isozaki et al., 2010) and Translation Error Rate (TER) (Snover et al., 2006).

3 Experiments

This section briefly describes the experiment settings for developing the systems.

3.1 Data Preparations

The parallel data-set for these experiments was provided by the *WMT Similar Translation Shared Task* [1] organisers and the Marathi monolingual data-set was taken from *WMT 2020 Shared Task: Parallel Corpus Filtering for Low-Resource Conditions*.[2] The parallel data was sub-divided into training, tuning, and monolingual sets, as detailed in Table 1. However, the shared data was very noisy.

To enhance the data quality, the team had to undertake an extensive pre-processing session focused on identifying and cleaning the data-sets. Out of 43274 training sentences, the Hindi corpus had Telugu sentences while the Marathi corpus had Meitei sentences intermingled as shown in first row (Figure 1). The parallel data had more than 1192 lines that were not comparable with each other as shown in second and third row (Figure 1), where some Hindi sentences had only half the sentences translated in Marathi (second row) and some had blank spaces against their Marathi counter parts (third row). The translation quality of the parallel data was also not up to mark. In fact, the team could locate a few instances of synthetic data. There were a few sentences where character encoding was an issue, hence were completely unintelligible.

Language Pair	Training	Tuning	Monolingual
Hindi ↔ Marathi	43274	1411	-
Marathi	-	-	326748
Hindi	-	-	75348193

Table 1: Statistics of Parallel and Monolingual Sentences of the Hindi and Marathi Languages

3.2 Pre-processing

The following pre-processing steps were performed as part of the experiments:

a) Both corpora were tokenized and cleaned (sentences of length over 80 words were removed).

b) For neural translation, training, validation and test data was prepossessed into subwords BPE format. This format was utilised to prepare BPE and vocabulary further used.

All these processes were performed using Moses scripts. However, the tokenization was done by the RGNLP team tokenizer (Ojha et al., 2018) and Indic_nlp_library.[3] These tokenizers were used since Moses does not provide a tokenizer for Indic languages. Also the RGNLP tokenizer ensured that the canonical Unicode representation of the characters are retained.

3.3 Development of the NUIG-Panlingua-KMI MT Systems

After removing noisy and pre-processing data, the following steps were followed to build the NUIG-Panlingua-KMI MT systems:

Figure 2: Analysis of the PBSMT and NMT's Systems

3.3.1 Building Primary MT Systems:

As previously mentioned, the Hindi-Marathi and Marathi-Hindi PBSMT systems were built as the primary submission using Moses. The language model was built first, using KenLM. For Marathi-Hindi and Hindi-Marathi language pairs, the language models were trained on 5-gram. After that, the systems were built independently and combined in a loglinear scheme in which each model was assigned a different weight using the Minimum Error Rate Training (Och, 2003) tuning algorithm. To train and tune the systems, we used 40454 and 1411

parallel sentences, respectively, for all language pairs.

3.3.2 Building Contrastive MT Systems:

As mentioned in the previous section, Nematus toolkit was used to develop the NMT systems. The training was done on subword and character-level. All the NMT experiments were carried out only with a data-set that contained sentences with length of up to 80 words. The neural model is trained on 5000 epochs, using Adam with a default learning rate of 0.002, dropout at 0.01 and mini-batches of 80 and the batch size for the validation was 40. Vocabulary size of 30000 for both Marathi-Hindi and Hindi-Marathi language pairs was extracted. Remaining parameters were limited with the use of default hyper-parameters configuration.

4 Evaluation

All the systems were evaluated using the reference set provided by the shared task organizers. The standard MT evaluation metrics, BLEU (Papineni et al., 2002) score, RIBES (Isozaki et al., 2010) and TER (Snover et al., 2006), were used for automatic evaluation. These results were prepared on the Primary and Contrastive system submission which are mentioned in the Table 2 as _P and _C, where *_P* stands for Primary and *_C* stands for Contrastive, respectively. It gives a quantitative picture of particular differences across different systems, especially with reference to evaluation scores (Table 2)

System	BLEU	RIBES	TER
Hindi-Marathi_P	9.38	51.88	91.24
Hindi-Marathi_C	9.76	52.18	91.49
Marathi-Hindi_P	17.38	59.31	81.47
Marathi-Hindi_C	17.39	58.84	81.15

Table 2: Accuracy of Hindi↔Marathi MT Systems at BLEU, RIBES and TER Metrics

4.1 Results

Overall we see varying performance among the system submitted to the task, with some performing much better out-of-sample than others. The NUIG-Panlingua-KMI subword NMT system took 8th position for both Hindi-Marathi and Marathi-Hindi language pair, across 14 teams. Our subword NMT systems for Marathi-Hindi language pair showed better results in terms of all the three metrics (17.39 in BLEU, 58.84 in RIBES and 81.15 in TER) while the Hindi-Marathi language pair scored 9.76 in BLEU, 52.18 in RIBES and 91.24 in TER. Across both the language pairs, subword based NMT performed better than PBSMT as its accuracy rate was higher in BLEU and lower in TER metrics, shown in Table 2.

4.2 Analysis

We used the reference set provided by the shared task organizers to evaluate both PBSMT and NMT systems. Even though subword based NMT system could take advantage of the shared features among similar languages, challenges in translating a few linguistics structures acted as a constraint. Example 1 shown in Figure 2 is one of the challenging structures that the system was unable to translate. In these sentences the systems could not capture the correct tense and aspect which is past perfect in source sentence whereas the NMT system translated it as simple past. The second most common challenging structures that needed special attention were the postpositions as shown in Example 2 and 3 in the figure. In most cases, the system over-generalised the sentences in Marathi and generated unnecessary postposition phrases in Hindi as in Example 2. Similarly, we can see in Example 3 while translating from Hindi to Marathi both PBSMT and NMT systems used wrong post-positions.

5 Conclusion

Our experiment results reveal that subword based NMT could take advantage of the relation between the similar language to boost the accuracy of neural machine translations system in low resource data settings. As BPE units are variable-length units and the vocabularies used are much smaller than morpheme and word-level model, the problem of data sparsity does not occur. On the contrary, it provides an appropriate context for translation between similar languages. However, the quality of data used to train the systems does affect the quality of translation. Thus, we could conclude that shared features between two languages could be an advantage to leverage the accuracy of NMT systems for closely related languages.

Acknowledgments

This publication has emanated from research in part supported by the Irish Research Council under grant number SFI/18/CRT/6223 (CRT-Centre for Research Training in Artificial Intelligence) co-funded by the European Regional Development Fund as well as by the EU H2020 programme un-

der grant agreements 731015 (ELEXIS-European Lexical Infrastructure).
We are also grateful to the organizers of WMT Similar Translation Shared Task 2020 for providing us the Hindi↔Marathi Parallel Corpus, monolingual and evaluation scores.

Neural Machine Translation for Similar Languages: The Case of Indo-Aryan Languages

Santanu Pal[1], Marcos Zampieri[2]
[1]Wipro AI Lab, India
[2]Rochester Institute of Technology, USA
santanu.pal2@wipro.com

Abstract

In this paper we present the WIPRO-RIT systems submitted to the Similar Language Translation shared task at WMT 2020. The second edition of this shared task featured parallel data from pairs/groups of similar languages from three different language families: Indo-Aryan languages (Hindi and Marathi), Romance languages (Catalan, Portuguese, and Spanish), and South Slavic Languages (Croatian, Serbian, and Slovene). We report the results obtained by our systems in translating from Hindi to Marathi and from Marathi to Hindi. WIPRO-RIT achieved competitive performance ranking 1st in Marathi to Hindi and 2nd in Hindi to Marathi translation among 22 systems.

1 Introduction

WMT 2020 is the fifth edition of WMT as a conference following a series of well-attended workshops that date back to 2006. WMT became a well-established conference due to its blend of research papers and popular shared tasks on different topics such as translation in various domains (e.g. biomedical, news), translation quality estimation, and automatic post-editing. The competitions co-organized with WMT provide important datasets and benchmarks widely used in the MT community. The vast majority of these tasks so far, however, involved training systems to translate to and from English (Bojar et al., 2016, 2017) while only a few of them addressed the problem of translating between pairs of languages with less resources.

To address this issue, in 2019, the Similar Language Translation (SLT) shared task was introduced at WMT. SLT's purpose was to evaluate the performance of state-of-the-art MT systems on translating between pairs of similar languages without English as a pivot language (Barrault et al., 2019). The organizers provided participants with training, development, and testing parallel data from three pairs of languages from three different language families: Spanish - Portuguese (Romance languages), Czech - Polish (Slavic languages), and Hindi - Nepali (Indo-Aryan languages). Systems were evaluated using automatic metrics, namely BLEU (Papineni et al., 2002) and TER (Snover et al., 2006).

In SLT 2020, the task organizes once again included an Indo-Aryan language track with Hindi and Marathi. Indo-Aryan languages are a sub-family of the Indo-European language family which includes Bengali, Bohjpuri, Hindi, Marathi, and Nepali. These languages are mainly spoken in North and Central India, and some neighbouring countries such as Nepal, Bangladesh, and Pakistan etc. The script used in most of these languages are derived from the ancient Brahmi script and enriched with high grapheme to phoneme correspondence leading to many orthographic similarities across these languages.

In addition to Hindi and Marathi, SLT 2020 features two other tracks with similar languages from the following language families: Romance languages (Catalan, Portuguese, and Spanish) and South Slavic Languages (Croatian, Serbian, and Slovene). In this paper we describe the WIPRO-RIT submission to the SLT 2020 Indo-Aryan track. Our WIPRO-RIT system is based on the model described in Johnson et al. (2017). WIPRO-RIT achieved competitive performance ranking 1st in Marathi to Hindi and 2nd in Hindi to Marathi translation among 22 systems.

Proceedings of the 5th Conference on Machine Translation (WMT), pages 424–429

2 Related Work

With the substantial performance improvements brought to MT by neural approaches, a growing interest in translating between pairs of similar languages, language varieties, and dialects has been observed. Recent studies have addressed MT between Arabic dialects (Harrat et al., 2019; Shapiro and Duh, 2019) Catalan and Spanish, Croatian and Serbian (Popović et al., 2020), (Costa-jussà, 2017), Brazilian and European Portuguese (Costa-jussà et al., 2018), and several pairs of languages and language varieties such as Brazilian and European Portuguese, Canadian and European French, and similar languages such as Croatian and Serbian, and Indonesian and Malay (Lakew et al., 2018).

The interest on diatopic language variation is evidenced by the recent iterations of the VarDial workshop in which papers on MT applied to similar languages varieties, and dialects (Shapiro and Duh, 2019; Myint Oo et al., 2019; Popović et al., 2020) have been presented along with evaluation campaigns featuring multiple shared tasks on a number of related topics such as cross-lingual morphological analysis, cross-lingual parsing, dialect identification, and morphosyntactic tagging (Zampieri et al., 2018, 2019; Găman et al., 2020).

3 Data

For our experiments, we use the Hindi–Marathi and Marathi–Hindi WMT 2020 SLT data. The released parallel dataset was collected from news (Siripragada et al., 2020), PMIndia (Haddow and Kirefu, 2020) and Indic Wordnet (Bhattacharyya, 2010; Kunchukuttan, 2020a) datasets. To augment our dataset, we use English–Hindi parallel data released in WMT 2014 (Bojar et al., 2014), consisting of more than 2 million parallel sentences, which is available as an additional resource. We use a subset of 5 million segments of Hindi monolingual news crawled from ca. 32 million data. We also use a subset 5 million Marathi monolingual data. We performed similar cleaning and pre-processing methods as we described in case of parallel data.

The five million Hindi monolingual sentences were first back-translated to English using a Hindi–English NMT system. The Hindi–English NMT system was trained on English–Hindi parallel data released in WMT 2014 (Bojar et al., 2014), IITB parallel corpus (Kunchukuttan et al., 2018), the parallel dataset was collected from news (Siripragada et al., 2020) and the PMIndia (Haddow and Kirefu, 2020) parallel corpus (see Table 1).

Data Sources	#sentences

Cleaning*	961,036

Table 1: English–Hindi parallel data statistics. *Removing noisy mixed language sentences.

We also back-translated 5 million Marathi monolingual sehments using our WIPRO-RIT CONTRASTIVE 1 system described in more detail Section 6. For Marathi–Hindi we did not use any back translation data in our CONTRASTIVE 2 and PRIMARY submissions. In the both cases 5 million English–Hindi back-translation data provide significant ($p < 0.01$) improvements over CONTRASTIVE 1 (detailed in Section 6).

The released WMT 2014 EN-HI data and the WMT SLT 2020 data were noisy for our purposes, so we apply methods for cleaning (see data statistics in Table 2).

Table 3: Multilingual **Processed data**, indicating TO_XX as target language:

moving duplicates, we have 1M EN-HI parallel sentences. Next, we perform punctuation normalization, and then we use the Moses tokenizer to tokenize the English side of the parallel corpus with 'no-escape' option. Finally, we apply true-casing. For the case of Hindi and Marathi, we use Indic NLP Library[1] (Kunchukuttan, 2020b) for tokenizaton.

4 Model Architecture

Our model is based on a transformer architecture (Vaswani et al., 2017) built solely upon such attention mechanisms completely replacing recurrence and convolutions. The transformer uses positional encoding to encode the input and output sequences, and computes both self- and cross-attention through so-called multi-head attentions, which are facilitated by parallelization. We use multi-head attention to jointly attend to information at different positions from different representation subspaces.

We present a single multilingual NMT system based on the transformer architecture that can translate between multiple languages. To make use of multilingual data within a single NMT model, we perform one simple modification to the source side of the multilingual data, we use an additional token at the beginning of the each source sentence to indicate the target language by the NMT model would be translated as shown in Table 3.

We train the model with all the processed multilingual data consisting of sentence aligned multiple language pairs at once, During inference, we also need to add the aforementioned additional token to each input source sentence of the source data to specify the desired target language.

5 Experiments

In the next sub-sections we describe the experiments we carried out for translating from Hindi to Marathi and from Marathi to Hindi for WIPRO-RIT's WMT 2020 SLT shared task submission.

5.1 Experiment Setup

To handle out-of-vocabulary words and to reduce the vocabulary size, instead of considering words, we consider subword units (Sennrich et al., 2016) by using byte-pair encoding (BPE). In the preprocessing step, instead of learning an explicit mapping between BPEs in the English (EN), Hindi (HI) and Marathi (MR), we define BPE tokens by jointly processing all parallel data. Thus, all derive a single BPE vocabulary. Since HI and MR belong to the similar languages, they naturally share a good fraction of BPE tokens, which reduces the vocabulary size.

We report evaluation results (evaluated by the shared task organizers) of our approach with the released Test data. BLEU (Papineni et al., 2002), RIBES (Isozaki et al., 2010) and TER (Snover et al., 2006) are used to evaluate the performance of all participating systems in the shared task.

Parallel Data	#sentences	C1	C2	P

Filtered EN–HI	961,036	✓	✓	✓
BT EN–HI	5 million	✓	✓	✓
BT HI–MR	5 million		✓	✓

Table 4: The training criteria data statistics of our submitted systems (C1 = Contrastive 1, C2 = Contrastive 2, P = Primary, and BT = Back-translated data).

5.2 Hyper-parameter Setup

We follow a similar hyper-parameter setup for all reported systems. All encoders, and the decoder, are composed of a stack of $N_X = 6$ identical layers followed by layer normalization. Each layer again consists of two sub-layers and a residual connection (He et al., 2016) around each of the two sub-layers. We apply dropout (Srivastava et al., 2014) to the output of each sub-layer, before it is added to the sub-layer input and normalized. Furthermore, dropout is applied to the sums of the word embeddings and the corresponding positional encodings in both encoders as well as the decoder stacks.

We set all dropout values in the network to 0.1. During training, we employ label smoothing with value $\epsilon_{ls} = 0.1$. The output dimension produced by all sub-layers and embedding layers is $d_{model} = 512$. Each encoder and decoder layer contains a fully connected feed-forward network (FFN) having dimensionality of $d_{model} = 512$ for the input and output and dimensionality of $d_{ff} = 2048$ for the inner layers. For the scaled dot-product attention, the input consists of queries and keys of dimension d_k, and values of dimension d_v. As multi-head attention parameters, we employ $h = 8$ for parallel attention layers, or heads. For each of these we use a dimensionality of $d_k = d_v = d_{model}/h = 64$. For optimization, we use the Adam optimizer (Kingma and Ba, 2015) with $\beta_1 = 0.9$, $\beta_2 = 0.98$ and $\epsilon = 10^{-9}$.

The learning rate is varied throughout the training process, and increasing for the first training steps $warmup_{steps} = 16000$ and afterwards decreasing as described in (Vaswani et al., 2017). All remaining hyper-parameters are set analogously to those of the transformer's *base* model. At training time, the batch size is set to 25K tokens, with a maximum sentence length of 256 subwords, and a vocabulary size of 32K. After each epoch, the training data is shuffled. During decoding, we perform beam search with a beam size of 4. We use 32K BPE operations to train our BPE models. We use shared embeddings in all our experiments.

6 Results

We present the results obtained by our systems for Hindi–Marathi in Table 5 and for Marathi–Hindi in Table 6 in terms of BLEU, RIBES, and TER. We apply our proposed method to train multilingual models in three different configurations. Table 4 shows different training data used to train our CONTRASTIVE 1 (C1), CONTRASTIVE 2 (C2) and Primary (P) submissions.

System	BLEU ↑	RIBES ↑	TER ↓
P	16.62	62.45	72.23
C2	15.42	61.02	73.59
C1	13.25	58.51	76.17

Table 5: Results for Hindi to Marathi translation ranked by BLEU score.

System	BLEU ↑	RIBES ↑	TER ↓
P	24.53	66.23	66.39
C2	22.93	65.89	68.11
C1	22.69	65.01	68.13

Table 6: Results for Marathi to Hindi Translation ranked by BLEU score.

CONTRASTIVE 1 (C1) Our CONTRASTIVE 1 submission is a multilingual single system and does not use any monolingual back translation data. The system is trained on the released HI-MR and MR-HI parallel data. In addition to we also use EN-HI parallel data.

CONTRASTIVE 2 (C2) This submission is similar to CONTRASTIVE 1, however in this case we used 5M back-translated Marathi–Hindi and 5M back-translated Hindi–Marathi corpus. Source back-translated sentences begin with an additional token indicating the target language.

PRIMARY (P) Our primary submission is trained using the same setting as we described in CONTRASTIVE 2 system. The difference is our primary system is an ensemble of three different CONTRASTIVE 2 systems initiated with three different random seeds.

7 Conclusion and Future Work

This paper presented the WIPRO–RIT system submitted to the Similar Language Translation shared task at WMT 2020. We presented the results obtained by our system in translating from Hindi to Marathi and Marathi to Hindi. Our primary system achieved competitive performance ranking first in Marathi to Hindi and second in Hindi to Marathi among 22 teams in terms of BLEU score.

In future work, we would like to further explore the similarity between these two languages in translating to other Indo-Aryan languages (e.g. Bengali, Bhojpuri, and Nepali). We expect the models presented in this paper to perform well for other Indo-Aryan language provided that suitable training data is available. Furthermore, we would like to apply and evaluate our method on the two other groups of languages in the WMT SLT 2020 shared task, Romance languages: Catalan, Portuguese, and Spanish, and South Slavic languages: Croatian, Serbian, and Slovene. Finally, we will be incorporating the translation models presented in this paper to CATaLog, an open-source online CAT tool that provides users with both MT and TM outputs (Nayek et al., 2015; Pal et al., 2016).

Acknowledgments

We would like to thank the WMT 2020 SLT shared task organizers for making the Hindi - Marathi data available. We further thank the anonymous WMT reviewers for their insightful feedback and suggestions.

Abstract

This paper describes the ADAPT-DCU machine translation systems built for the WMT 2020 shared task on Similar Language Translation. We explored several set-ups for NMT for Croatian–Slovenian and Serbian–Slovenian language pairs in both translation directions. Our experiments focus on different amounts and types of training data: we first apply basic filtering on the *OpenSubtitles* training corpora, then we perform additional cleaning of remaining misaligned segments based on character n-gram matching. Finally, we make use of additional monolingual data by creating synthetic parallel data through back-translation. Automatic evaluation shows that multilingual systems with joint Serbian and Croatian data are better than bilingual, as well as that character-based cleaning leads to improved scores while using less data. The results also confirm once more that adding back-translated data further improves the performance, especially when the synthetic data is similar to the desired domain of the development and test set. This, however, might come at a price of prolonged training time, especially for multitarget systems.

1 Introduction

Machine translation (MT) between closely related languages is, in principle, less challenging than translation between distantly related languages, but it is still far from being solved. While MT between closely related South-Western Slavic languages, Croatian, Slovenian and Serbian based on the rule-based (RBMT) and the phrase-based (PB-SMT) approaches has been investigated in the last years (Etchegoyhen et al., 2014; Petkovski et al., 2014; Klubička et al., 2016; Arčan et al., 2016; Popović et al., 2016a), to the best of our knowledge, the new state-of-the-art neural machine translation (NMT) has not been investigated yet for these languages.

In this work, we first compare bilingual and multilingual systems in order to determine whether joining Serbian and Croatian data is useful. Afterwards, we investigate additional cleaning of remaining misaligned segments by using character n-gram matching scores (Popović, 2015). The beauty of the method for similar languages is that it can be applied directly to the given training corpus providing matching scores for each pair of the source-target segments. For distant languages, translation of one side of the training corpus would be required. Finally, we make use of monolingual data in each of the three languages by creating additional synthetic parallel training sets via back-translation (Sennrich et al., 2016a; Poncelas et al., 2018; Burlot and Yvon, 2018).

2 Language properties

Common properties All three languages, Croatian, Serbian and Slovenian, belong to the South-Western Slavic branch. As Slavic languages, they have a very rich inflectional morphology for all word classes: six cases and three genders for all nouns, pronouns, adjectives and determiners. For verbs, person and many tenses are expressed by the suffix so that the subject pronoun is often omitted. There are two verb aspects, so that many verbs have perfective and imperfective form(s) depending on the duration of the described action. As for syntax, all three languages have quite a free word order, and neither language uses articles, either definite or indefinite. In addition to this, multiple negation is always used.

Croatian and Serbian Croatian and Serbian exhibit a large overlap in vocabulary and a strong morpho-syntactic similarity so that the speakers can understand each other without difficulties. Nev-

Proceedings of the 5th Conference on Machine Translation (WMT), pages 430–436

ertheless, there is a number of small but notable and also frequently occurring differences between them. The largest differences between the two languages are in vocabulary: some words are completely different, some however differ only by one or two letters. Apart from lexical differences, there are also structural differences mainly concerning verbs: modal verb constructions, future tense, as well as conditional.

Slovenian Even though Slovenian is very closely related to Croatian and Serbian, and the languages share a large degree of mutual intelligibility, a number of Croatian/Serbian speakers may have difficulties with Slovenian and the other way round. The nature of the lexical differences is similar to the one between Croatian and Serbian, namely a number of words is completely different and a number only differs by one or two letters. However, the amount of different words is much larger. In addition to that, the set of overlapping words includes a number of false friends (e.g. *brati* means *to pluck* in Croatian and Serbian but *to read* in Slovenian).

The amount of grammatical differences is also larger and includes local word order, verb mood and/or tense formation, question structure, usage of cases, structural properties for certain conjunctions, as well as some other structural differences. Another important difference is the Slovenian dual grammatical number which refers to two entities (apart from singular for one and plural for more than two). It requires additional set of pronouns, as well as additional sets for noun, adjective and verb inflexion rules not existing either in Croatian or in Serbian.

3 Data

For training, we used publicly available OPUS[1] parallel corpora (Tiedemann, 2012) indicated by the workshop organisers. *OpenSubtitles* is indicated for all translation directions. For Croatian–Slovenian, other corpora are indicated too, but they are either not sentence-aligned (*JW300*) or are extremely noisy (*DGT, MultiParaCrawl*). Therefore, we decided to use only *OpenSubtitles* for all translation directions.

It is worth noting that the organisers also indicated the *SETIMES News* parallel Croatian–Serbian corpus. Developing an additional Croatian–Serbian MT system for converting Serbian data into Croatian and vice versa was shown to be helpful for the PBSMT approach (Popović and Ljubešić, 2014; Popović et al., 2016b). However, our preliminary experiments in this direction indicated that this technique is not helpful for the NMT approach.

	dev	*PR publications*	1259
	test	*PR publications*	1260

Table 1: Corpus statistics.

The original parallel data were filtered in order to eliminate noisy parts: too long segments (more than 100 words), segment pairs with disproportional sentence lengths, segments with more than 1/3 of non-alphanumeric characters, as well as duplicate segment pairs were removed. The statistics of the remaining subtitles together with the development and test sets is shown in Table 1. The development and test sets were provided by the organisers and originate from Public Relations publications of a business intelligence company.

3.1 Additional cleaning of *OpenSubtitles*

While a large number of noisy parts and misaligned segments was removed from *OpenSubtitles* by the basic filtering procedure, a number of misaligned segments still remained. In order to remove these, we applied additional cleaning based on the character n-gram F-score chrF usually used for MT evaluation (Popović, 2015). For the purpose of cleaning, the chrF score is calculated for each pair of segments in the training data. Due to similarity between the languages, the scores between the properly aligned segments are higher than the scores of misaligned segments. Nevertheless, the languages are sufficiently different so that some properly aligned short segments (or single words) can have low scores, too. Still, if those words also appear in longer sentences, they will not be removed. Preliminary experiments with different thresholds showed that keeping the segments with the chrF score equal or greater than 20 is the best option.

3.2 Using monolingual data

In addition to the parallel *OpenSubtitles* corpora, we also used the monolingual data in each of the three languages which were indicated by the organisers, namely the mixed-domain data collected from Web, *hrWac*, *slWac* and *hrWac* (Ljubešić and Erjavec, 2011; Ljubešić and Klubička, 2014). As a first step, we removed too long and too short sentences, keeping those between 5 and 60 words. Then, we removed sentences with more than 1/3 of non-alphanumeric characters, sentences with URLs, as well as duplicate sentences.

Then, we wanted to rank these sentences according to the relevance for our experiments, namely according to their similarity to the development corpus. For this purpose, we used Feature Decay Algorithm (FDA) (Biçici and Yuret, 2011). This method iteratively selects sentences from an initial set S based on the number of n-grams which overlap with an in-domain text $Seed$ and adds these sentences to a selected set Sel. In addition, in order to promote a diversity, after a sentence is selected, its n-grams suffer a penalisation so that they are less likely to be selected in the following iterations. The default FDA system halves the score of an n-gram each time it is selected. Therefore the score of a sentence s is computed as in Equation (1):

$$score(s, Seed, Sel) = \frac{\sum_{ngr \in \{s \bigcap Seed\}} 0.5^{C_{Sel}(ngr)}}{\text{length(s)}} \quad (1)$$

where Sel is the set of sentences that have been selected and $C_Sel(ngr)$ is the count of occurrences of the *n*-gram ngr. At the end, the set S is converted into the set Sel containing the same sentences, but ranked according to their relevance.

For our experiments, the *hrWac*, *slWac* and *srWac* corpora represented the sets S, and the development sets in the corresponding target language were used as $Seed$.

Back-translated synthetic parallel corpora After ranking the monolingual corpora by FDA, back-translation was applied in order to create additional parallel training corpora. For each translation direction, the first two million best ranked sentences in the target language were translated into the source language by the corresponding NMT system.

Translation from Slovenian: The first two million best ranked Serbian sentences and the first two million best ranked Croatian sentences were translated into Slovenian.

Translation into Slovenian: Slovenian is the target language for two translation directions, and we wanted to have equally relevant Slovenian sentences for both directions. Therefore, we did not take the first two million sentences for one source language and the second two million for the other, because the Slovenian sentences for the first source language would be more relevant than those for the second source language. Instead, we took the first four million best ranked Slovenian sentences, and then translated every odd sentence into Serbian and every even sentence into Croatian.

4 MT systems

All our systems are built using the Sockeye implementation (Hieber et al., 2018) of the Transformer architecture (Vaswani et al., 2017). The systems operate on sub-word units generated by byte-pair encoding (BPE) (Sennrich et al., 2016b). We set the number of BPE merging operations at 32000. We use shared vocabularies between the languages because they are similar. Multilingual systems are built using the same technique as (Johnson et al., 2017) and (Aharoni et al., 2019), namely adding a target language label "SR" or "HR" to each source sentence. We investigated the following set-ups:

1. Systems trained on *OpenSubtitles*

   The four bilingual systems, HR→SL, SR→SL, SL→HR and SL→SR, are trained separately for each language pair and each translation direction on about 11M parallel segments.

   The multisource system HR+SR→SL is trained for translation into Slovenian by joining Serbian and Croatian sources and removing duplicates, thus resulting in 20.2M parallel segments.

   The multitarget system SL→HR+SR is trained for translation from Slovenian on the reversed corpus of 20.2M segments with target language identificators "SR" and "HR" added to the source side.

2. Systems trained on cleaned *OpenSubtitles*

   Two multilingual systems HR+SR→SL_CLEAN and SL→HR+SL_CLEAN are trained on joint *OpenSubtitles* corpora additionally cleaned by the chrF score. The

cleaned corpus consists of 10.8M segments (instead of 20.2M).

3. Systems trained on cleaned *OpenSubtitles* and synthetic back-translated parallel *Wac* data

   Two multilingual systems HR+SR→SL_CLEAN+BT and SL→HR+SR_CLEAN+BT are trained on joint cleaned *OpenSubtitles* corpora together with the corresponding synthetic back-translated data selected from *hrWac*, *slWac* and *srWac*. The monolingual data was back-translated by the corresponding systems trained on cleaned *OpenSubtitles*. The training corpora consist of 14.8M segments.

5 Results

We evaluate our systems using the following three automatic overall evaluation scores: sacreBLEU (Post, 2018), chrF (Popović, 2015) and characTER (Wang et al., 2016). The BLEU score is used because of the long tradition. The two character level scores are shown to correlate much better with human assessments (Bojar et al., 2017; Ma et al., 2018), especially for morphologically rich languages. In addition, the chrF score is recommended as a replacement for BLEU in a recent detailed study encompassing a number of automatic MT metrics (Mathur et al., 2020). In addition to the automatic MT evaluation scores, for each of the systems we report the size of the training corpus and the training time.

Table 2 shows the results both on the development and on the test set for each of the four translation directions. First of all, it can be seen that the automatic scores are relatively low given the similarity of the languages. One reason is domain/genre discrepance between the training and the development/test sets. Another possible reason is the nature of the *OpenSubtitles* corpus. The majority of non-English texts in *OpenSubtitles* are namely human translations from English originals. Therefore, for translation from English, the source language is the original one and the target language is its human translation.[2] On the other hand, for translation not involving English, both sides are human translations, which can have a strong impact on performance (Kurokawa et al., 2009; Vyas et al., 2018; Zhang and Toral, 2019). These effects should be investigated in future work.

[2] And other way round for translation into English.

Results on the development set For the systems trained on *OpenSubtitles*, it can be seen that for each translation direction, multilingual systems yield better automatic scores than bilingual systems at the cost of slightly prolonged training time (from about 3 days to 3-4 days). Therefore we choose the two multilingual systems HR+SR→SL and SL→HR+SR as the baselines and we did not keep the bilingual systems for further experiments.

The chrF cleaning of *OpenSubtitles* reduces the size of the corpus and the training time while slightly improving automatic scores. The reduction in time is slightly smaller for the multitarget translation from Slovenian (down to 2-3 days) than for the multisource translation into Slovenian (down to less than 2 days).

Adding the back-translated data from *Wac* improves the automatic scores for more than 10 points for multisource translation (into Slovenian) and for 5 to 10 points for multitarget translation (from Slovenian). This could be expected, especially since the monolingual data was chosen to be similar to the development data. Nevertheless, this large improvement comes at a price. Although the increase of the corpus is not very large, from 10.8M to 14.8M, the training time increases to (more than) 3 days. It can be noted that for some set-ups, the multitarget system needs more training time. The probable reason is the diversity of the target part of the training corpus – the system has to deal with two target languages, and when synthetic data is added, also with two different domains/genres for each of them.

Results on the test set Based on the results on the development set, we submitted the outputs of the systems with back-translated data (HR+SR→SL_CLEAN+BT, SL→HR+SR_CLEAN+BT) as primary submissions. The outputs of the systems trained on cleaned data (HR+SR→SL_CLEAN, SL→HR+SR_CLEAN) were submitted as first contrastive, and the outputs of the baseline multilingual systems (HR+SR→SL, SL→HR+SR) as second contrastive submissions. The test sets were not at all translated by the initial bilingual systems, therefore the results are not available.

It can be seen that the tendencies for the test set are almost the same as for the development set. The only difference is the larger improvement obtained by cleaning *OpenSubtitles* with the chrF scores. Further detailed analysis involving manual inspec-

6 Summary and outlook

This work investigates different set-ups for training NMT systems for translation between three closely related South-Slavic languages: Slovenian on one side, and Serbian and Croatian on the other side. We explore different sizes and types of training corpora, as well as bilingual and multilingual systems. Our results show that for all translation directions, multilingual systems with joint Croatian and Serbian data perform better than bilingual systems. The results also show that cleaning misaligned segments using character n-gram matching (chrF score) represents a fast and useful method for closely related languages, which improved the evaluation scores while reducing corpus size and training time. Finally, we confirm that adding back-translated synthetic data, which is the usual practice in neural machine translation, can yield large improvements of evaluation scores also for these languages. Nevertheless, for multitarget translation, it might result in a prolonged training time due to increased variety of the target language side.

Future work should include more genres and domains, as well as detailed analysis of errors and problems in order to further improve the performance of NMT between South Slavic languages.

Abstract

This paper describes Infosys' submission to the WMT20 Similar Language Translation shared task. We participated in Indo-Aryan language pair in the language direction Hindi to Marathi. Our baseline system is byte-pair encoding based transformer model trained with the fairseq sequence modeling toolkit. Our final system is an ensemble of two transformer models, which ranked first in the WMT20 evaluation. One model is designed to learn the nuances of translation of this low resource language pair by taking advantage of the fact that the source and target languages are the same alphabet languages. The other model is the result of experimentation with the proportion of back-translated data to the parallel data to improve translation fluency.

1 Introduction

Neural Machine Translation (Bahdanau et al., 2015; Vaswani et al., 2017) is the most popular approach for machine translation. Transformer-based NMT has outperformed many recurrent neural network based models. There is scope for improvement in NMT, particularly for low-resource language pairs.

Our techniques are experimented on the fairseq sequence modeling toolkit (Ott et al., 2019) for NMT. Our system is an ensemble of two transformer-based models. One designed for low-resource language pairs by taking advantage that both are same alphabet languages. The other model is built after experimenting on renowned back-translation technique (Sennrich et al., 2016a) by exploiting target monolingual data.

2 Data

Hindi-Marathi bitext data contains ∼49K sentence pairs. Target monolingual data comprises of 326K Newscrawl sentences and 10,839K raw sentences.

2.1 Data Preprocessing

Typical training sentence pairs comprises of a source and a target sentence. There are ∼1K training sentence pairs where source or target contains multiple sentences delimited by '/'. Matching pair for these sentences is derived based on the proximity of token lengths between source and target sentence.

Non-printable characters are removed, punctuations are normalized, and the data is tokenized, with the Moses tokenizer. Byte-pair encoding (BPE) has been adopted (Sennrich et al., 2016a) to build source and target sub-word vocabularies of size 22.5K and 32.8K respectively, when configured to construct with 60K symbols.

2.2 Data filtering

2.2.1 Bitext data

Sentences with more than 175 words, sentences with no words, and sentence pairs exceeding length ratio of 1.5 are removed from training data. This eliminated around 18% of the overall real bitext data.

2.2.2 Synthetic data

CommonCrawl n-grams raw monolingual files are processed[1] to remove sentences with invalid characters, strip leading and trailing whitespaces, and remove duplicate sentences.

3 System Overview

Our Hindi-Marathi primary system is an ensemble of two transformer models. One is back-translated model and the other model is trained on anonymized data.

[1] https://github.com/kpu/preprocess

Proceedings of the 5th Conference on Machine Translation (WMT), pages 437–441
Online, November 19–20, 2020.

3.1 Base Model Architecture and Hyperparameters

Our model is built using fairseq[2] (Ott et al., 2019) toolkit. The Transformer, an encoder-decoder architecture (Vaswani et al., 2017), with 6 layers for the encoder and 6 layers for the decoder, and with 8 heads in all multi-head attention layers, is our base model. Embedding dimension is set to 512 and feed-forward size (FFN) is set to 2048. Our model is trained on single GPU with maximum tokens per GPU set to 4096. The batch size multiplier is set to 8. Dropout probability of 0.3 and label smoothing probability of 0.1 is applied to avoid overfitting. Adam optimizer is used with $\beta_1 = 0.9$, $\beta_2 = 0.98$. The model is trained with an initial learning rate of 5e-4 and 4000 warm-up updates. The ensemble model prepared by averaging last 3 checkpoints is used for inferencing. Reported detokenized test BLEU is 9.13 for the provided dev dataset.

Parameters are tuned, following Baquero-Arnal et al. (2019). Threshold frequency is set such that only tokens occurring at least 10 times in the training data will be part of the vocabulary. Maximum tokens per GPU is set to 4000 and the batch size multiplier is fixated to 4 to set an effective batch size of 16000 tokens with dropout probability of 0.1. This led to improved performance. Reported detokenized test BLEU is 14.13 and hence these settings are adapted.

3.2 Backtranslation

Back-translation is a popularly adapted data augmentation technique which aids in building better NMT systems, especially for low resource language pairs by leveraging monolingual corpora (Sennrich et al., 2016a). An intermediate system is first trained on parallel data which is used to translate target monolingual data into source language. Sampling is used as a method for inference (Edunov et al., 2018). Synthetic parallel data is constructed from the intermediate system generated synthetic source while the target is the provided monolingual data. The Bitext data filters are also applied to synthetic data but only removed sentences with more than 250 words. New training data is constructed by appending this synthetic parallel data to real bitext data and a final system that will translate from the source to the target language will be trained.

[2]https://github.com/pytorch/fairseq

3.2.1 Bitext and Synthetic corpora proportion

Related Work Real to synthetic parallel data close to 1-to-1 proportion works best for Sennrich et al. (2016a). Junczys-Dowmunt et al. (2016), also chose 1-to-1 ratio of real to synthetic parallel data for English-Russian news translation task. It is also known from past experiments that increasing the ratio of synthetic training data erratically, degrades system performance, depending on quality and domain of synthetic data (Sennrich et al., 2016a; Currey et al., 2017; Poncelas et al., 2018).

In contrast, experiments conducted by Stahlberg et al. (2018), shows that performance of system does not reduce as long as the ratio of real parallel to synthetic parallel data does not exceed 1-to-8 (1.6M out of 3M Turkish monolingual data is preferred for training along with 0.2M of parallel corpus for English-Turkish). Fadaee and Monz (2018), claims, 1-to-5 real to synthetic parallel data ratio achieved best performance in news translation task for German-English with 4.5M parallel corpus.

This limits from taking advantage of all available monolingual corpus. Only a small portion of it can be used as synthetic parallel training data. Oversampling (Chu et al., 2017; Junczys-Dowmunt and Grundkiewicz, 2018) real parallel data can overcome this problem. By oversampling primary parallel data equivalent to the synthetic parallel data from all monolingual data, effective 1-to-1 ratio of bitext and synthetic parallel data can be retained.

Experiment 1-to-1 ratio of bitext to synthetic data is chosen after experimentation with ratios (see Table 1, Figure 1).

Ratio	BLEU
Baseline (1:0)	14.13
1:0.5	18.08
1:1.0	18.76
1:2.5	16.20
1:5.0	14.49
All monolingual data (1:78.0)	11.01

Table 1: BLEU score for different bitext and synthetic corpora proportion

It is crucial to find the ideal proportion of synthetic data to use. Utilization of all available out-of-domain and raw monolingual corpora to the maximum effect can be further explored.

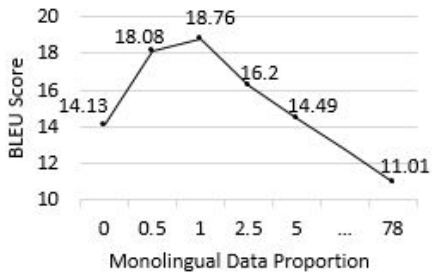

Figure 1: BLEU score for different bitext and synthetic corpora proportion

3.2.2 Out-of-domain data

Handling OOV BPE is applied on monolingual target data using byte pairs learnt during bitext BPE operation. Out-of-vocabulary (OOV) tokens in BPE applied monolingual target data are the tokens not in bitext vocabulary. These out-of-vocabulary tokens are replaced by a special symbol UNK in the monolingual target data (see Table 2).

Considered	Filtered	OOV
25K	19K	16.5%
50K	35K	17.9%
100K	72K	22.0%
300K	172K	21.2%
11.2M	2.5M	23.0%

Table 2: Out-of-domain words in target monolingual data. "Considered" represents the amount of target monolingual data used for study. "Filtered" represents the amount of target monolingual data after applying filters.

Experiment Since the intermediate model spot UNK symbol in the inputs during inferencing, inferenced data also contains UNK symbol.

Gulcehre et al. (2015), claims to eliminate monolingual sentences with more than 10% UNK symbols for better performance. Sennrich et al. (2016b), claims to handle rare/unseen words by representing it in a sequence of sub-word units using existing vocabulary that was learnt on the parallel data. Our systems are experimented by excluding sentences with UNK symbol.

Systems are trained with different proportions of real to synthetic data by eliminating all sentence pairs containing UNK in training data. Table 3 shows the study of model performance before and after removing sentence pairs containing UNK. 1-to-1 proportion of real and synthetic data with out-of-vocabulary tokens masked by UNK symbol scored best (18.76) out of all outcomes.

Ratio	All Data	Data without UNK
1:0.5	18.08	17.73
1:1.0	18.76	18.34
1:5.0	14.49	16.60

Table 3: BLEU scores on models with and without removing sentences containing UNK

3.3 Anonymization

Analysis of the results of the model achieved 18.76 BLEU score, reveals that the translation accuracy is negatively impacted when UNK is generated. This is handled by building another model with bitext data only, where the similarity between source and target languages are anonymized by masking. This approach enables the model to specifically focus on learning the nuances of translation only (i.e.., enables the model to focus on the specific section in the source sentence that gets altered during translation).

Language pair comprising same alphabetic languages contains same words between them carrying similar meaning. Numbers, names, geographic names, etc., also holds same script. i.e. tokens that are not language specific. The approach here is to anonymize those words which are equally present in source and target sentences. One special character is used to mask all those tokens. The special character is chosen in place of a special word to eliminate the possibility of splitting the special word during sub-word tokenization.

This approach reduces the vocabulary size and the learning parameters of the model, preserving the context. This results in transforming sentences which appeared to be different in its raw form into duplicate sentences in its anonymized form, which are then deduplicated.

Hi-Mr track with ∼49K training sentences without masking technique generated source and target vocabulary of size 22.5K and 32.8K respectively. Anonymization reduced source and target vocabulary size to 20.9K and 31.0K respectively. This approach resulted in improvement of BLEU score by 1.2 over baseline. The impact of this approach is proportional to the similarity of source and target languages. The key observation is that this model performed better at translation of sentences that are translated poorly (with UNK tokens) by back-translation model.

3.4 Stacking

Benefits of both the masking systems (masking OOV tokens with UNK symbol and masking similar tokens) are attained through stacking. Model trained on anonymized parallel data and the model trained on real bitext plus synthetic parallel data are ensembled to achieve 19.76 BLEU with Dev data.

3.5 Post-processing

The anonymized words are preserved before inferencing and the inference results are decoded by replacing the special symbols with the preserved anonymized tokens followed by BPE detokenization.

4 Results

Our novel anonymization technique improved BLEU by 1.2. Optimal proportion of back-translated data improved BLEU by 3.5. Ensembling best systems improved BLEU by 1.0. (See Table 4)

System	Dev BLEU
Baseline	9.13
+hyperparameter tuning	14.13
+anonymization	15.46
Baseline	9.13
+hyperparameter tuning	14.13
+backtranslation	18.76
Ensemble	19.71

Table 4: BLEU scores on Hindi-Marathi

Our final submission to the competition in Hindi-Marathi track achieved 18.26 BLEU and ranked first among all submissions.

5 Conclusion

This paper describes the techniques involved in our system submitted for the WMT20 Similar Language Translation task by Infosys. This winning Hindi-Marathi translation system is built based on NMT and evaluated based on the metric, BLEU.

The domain-based data preprocessing and filtering techniques eases model learning. Adopting novel approach of anonymizing language agnostic tokens aided our system to focus more on tokens that matters in the translation. It is highly observed that the ratio of monolingual data used against bitext data plays a vital role in back-translated models. Improving translation accuracy and language fluency by utilizing all available out-of-domain monolingual corpora to the maximum effect can be further explored.

Abstract

This paper describes our system submission to WMT20 shared task on similar language translation. We examined the use of document-level neural machine translation (NMT) systems for low-resource, similar language pair Marathi−Hindi. Our system is an extension of state-of-the-art Transformer architecture with hierarchical attention networks to incorporate contextual information. Since, NMT requires large amount of parallel data which is not available for this task, our approach is focused on utilizing monolingual data with back translation to train our models. Our experiments reveal that document-level NMT can be a reasonable alternative to sentence-level NMT for improving translation quality of low resourced languages even when used with synthetic data.

1 Introduction

With the widespread use of MT systems in commercial and research community, there is an increased attention to train NMT models for direct translation between language pairs other than English Barrault et al. (2019). This is because of the growing need to translate between pairs of similar languages without considering English as pivot language. The task is to overcome the challenge of limited availability of parallel data by exploiting the advantages of similarity between languages when building machine translation models. Similar languages have the advantage of having some magnitude of common information such as lexical and semantic structures. A number of research studies have been published to exploit commonalities when translating text between close language pairs Pourdamghani and Knight (2017); Lakew et al. (2018); Costa-jussà (2017).

This paper describes our system submission at WMT shared Similar Language Translation task[1] which focuses on improving translation quality of similar languages in low-resource setting, the detail of task is provided in Barrault et al. (2019). This year's task includes five pairs of languages from three different language families i.e. Indo-Aryan, Romance and South-Slavic languages; we participated for Hindi-Marathi language pair. Since we are using NMT which requires large bitext, we need to alleviate this specific problem of bitext shortage. Sennrich et al. (2016) introduced an approach to utilize monolingual data using back translation. This requires a machine translation system in opposite direction to generate synthetic parallel corpora from target side monolingual text.

Our work is an attempt to investigate the translation of a similar language pair (Marathi-Hindi) using document-level NMT and back translation. We participated under team name "FJWU_NUST". We submitted one constrained system i.e. we only used the parallel and monolingual data provided by WMT20[2] organizers to train and evaluate our models. We train and evaluate NMT systems in both directions (i.e. HI⇒MR and MR⇒HI) but our submission to similar language shared task comprises of MR⇒HI systems only.

The rest of the paper is structured as follows: In Section 2 we give a brief background of document-level NMT, Section 3 presents utilization of monolingual data, Section 4 and 5 present our experimental setup and results. We conclude the paper in Section 6.

2 Document-Level NMT

Standard NMT works by translating individual sentences and focuses on short context windows while ignoring cross-sentence links and dependencies Xiong et al. (2019). Document-level NMT aims to consider discourse dependencies across sentences

[1] http://www.statmt.org/wmt20/similar.html

[2] http://www.statmt.org/wmt20/.

Proceedings of the 5th Conference on Machine Translation (WMT), pages 442–446

to capture document wide context. Most recently, there has been great interest in modelling larger context in standard NMT (Voita et al., 2018; Wang et al., 2017; Tu et al., 2018; Maruf and Haffari, 2017; Bawden et al., 2017; Jean et al., 2017; Chen et al., 2020). Cache based Tu et al. (2018) memory models can be used to hold rich information, can also provide the context of document during translation. Memory networks keep the representation of a set of words in cache to provide contextual information to NMT in the form of words. Kuang et al. (2017) used two caches, dynamic cache to capture dynamic context by storing words of translated sentence and topic cache which stores topical words of target side from entire document. Through a gating mechanism, the probability of NMT model and cache based neural model is combined to predict the next word. Miculicich et al. (2018) has proposed to use hierarchical attention network (HAN) Yang et al. (2016) to provide dynamic contextual information to NMT during translation. HANs are used on both sides, encoder and decoder to integrate source and target side context in NMT. In contrast to Recurrent Neural Networks (RNN), HANs provide dynamic access to contextual information during training and evaluation.

Similarly, Maruf and Haffari (2018) used pretrained RNN encoder to attach global source and target context to sentence based NMT. Zhang et al. (2018) has shown that integration of short context (2 sentences) outperforms existing cache based RNNSearch model. Voita et al. (2018) introduce a context aware NMT model with additional multi-head attention component, in which they control and analyze the flow of information from the extended context to the translation model.

Stojanovski and Fraser (2020) studied the use of Transformer based document-level models adoptable to novel (zero-resource) domains. They have shown the implicit domain adaptation of document-level NMT models trained on multi-domain data, is capable of capturing large context. The challenge of translating single sentences efficiently while keeping models insensitive to enlarge and noisy context is addressed by Zheng et al. (2020). To make general purpose context-aware MT, both for short and long sentences, they opt for having independent global and local context integration into sentence based NMT.

3 Utilizing Monolingual Data

Large amounts of monolingual resources are generally available for a multitude of languages. Back translation is considered a well known approach to mitigate the need of large parallel corpora by automatically translating target language monolingual data to source language Sennrich et al. (2016). Back translation requires a MT system in opposite direction, where target side monolingual data is translated into source text to generate synthetic parallel training data. Several techniques exists to utilize monolingual text for improving NMT (Abdul-Rauf et al., 2016; Zhang and Zong, 2016; Currey et al., 2017; Domhan and Hieber, 2017).

Document-level models require parallel data with document boundaries for training and evaluation. As compared to sentence-level systems, data for building robust document-level models is significantly low resourced Liu and Zhang (2020). WMT20 provides document-level distinctions for Europarl v9, New-Commentary v14 and Rapid corpus. Our training data is constrained to have only parallel and monolingual data provided by WMT20 shared task, the statistics of data are given in section 4.1. Since, our system is build in Marathi-Hindi direction, we backtranslated Hindi (News Crawl2008-2019) monolingual data into Marathi to generate bitext. This backtranslated data is than concatenated with parallel data made available by organizers, to train machine translation models.

4 Experimental Setup

For our primary submission we use document-level Miculicich et al. (2018) model, an extension of transformer with additional context attentions. For comparison with sentence-based NMT systems, a strong baseline using OpenNMT-py Klein et al. (2017) is first defined. For true comparison, the architecture and configurations of both the models are kept the same.

4.1 Dataset

Table 1 presents details of training, development and test corpus. We used all the parallel data (HI, MR) provided by WMT20 for similar language translation task. The available parallel data was insufficient to train NMT models, therefore we used monolingual "News Crawl" data for generating synthetic parallel corpus through backtranslation. NMT models are trained on backtranslated bitext combined with existing parallel corpus. Training

corpus contains data of multiple domains, a self test set is created by selecting chunk of data from each domain according to size of dataset. Original bitext and backtranslated parallel training data is tokenized with Indic-NLP [3] library, which supports tokenization/de-tokenization of Hindi and Marathi.

Our document-level systems Miculicich et al. (2018) expect document boundaries in text file during training and testing. Available data for this shared task does not contains document boundaries, for this we followed the same approach used by Ul Haq et al. (2020) to generate artificial document boundaries. They have taken average document size from document-level corpora and used the same size to generate document boundaries for parallel data without document distinctions. For train and dev set, instead of splitting on sentences, they considered number of documents. We have used average of two best performing context variables for document size as reported in Table 3 of Miculicich et al. (2018).

Corpus	Sentences	Documents
News	12.3K	4.1K
PmIndia	25.9K	8.6K
IndicWordNet	11.2K	3.7K
NewsCrawl-Monolingual	0.6M	0.2M
Dev	1114	278
Test	1941	485

Table 1: Train, Dev and Test dataset statistics along with document split.

4.2 Model Configurations

As our sentence-level baseline and document-level systems are based on Transformer model, we followed similar configuration parameters for both as reported in original paper Vaswani et al. (2017). 6 hidden layers are incorporated on both encoder and decoder side of Transformer model. All the hidden states have a dropout of 0.1 and 512 dimensions. Transformer model is trained with 8000 warm-up steps with a learning rate of 0.01. We checkpoint the model every 1000 steps for validation. For all the models, batch size is set to 2048 and is trained for 150 epochs.

Two step training process is followed as described by Miculicich et al. (2018). Initially NMT models are optimized without considering contextual information, after that encoder and decoder models are optimized by using context-aware HANs. HAN Transformer models gave best performance for 1-3 previous sentences, we use k=3 previous sentences for both source and target side context.

5 Results

Table 2 shows our results for Hindi−Marathi translations. Our document-level systems for both directions HR⇒MR and MR⇒HI outperformed sentence-level baselines.

BLEU score for WMT, Dev and $Self$ test set is reported in Table 2 for all systems. BLEU score for WMT test data is provided by WMT20 organizers. We have computed BLEU scores using Moses $multi - blue.perl$ script. For submission, we used output of document-level system trained on all data in MR⇒HI direction which gave highest BLEU score (6.79) on WMT test set. Our document-level models are optimized by adding context-aware HANs on encoder side only[4]. With DL−NMT model trained on corpus containing 90% backtranslated data, a gain of 0.63 BLEU points is achieved (6.16 ⇒ 6.79) over sentence-level baseline (row 2).

In last rows (3 and 4) of Table 2, NMT models are build in opposite direction of backtranslated data, depicted as $\text{NMT}_{\text{forward}}$ and and $\text{DL}-\text{NMT}_{\text{forward}}$. For forward translation models, source side is backtranslated data while target side is original monolingual data used for backtranslation. Similarly, DL−NMT models trained in forward direction of data, achieved batter score over NMT systems. Since, the large portion of training data contains synthetic data, on self test set all models performed better due to over fitting.

System	Direction	$BLEUScore$		
		Wmt	Dev	Self
NMT	MR⇒HI	6.16	8.08	12.50
+DL−NMT	MR⇒HI	**6.79**	9.31	14.93
$+\text{NMT}_{\text{fwd}}$	HI⇒MR	3.29	6.33	16.69
$+\text{DL}-\text{NMT}_{\text{fwd}}$	HI⇒MR	3.54	6.28	17.75

Table 2: Table summarizing Document-level NMT (DL-NMT) and NMT Transformer results for different test sets.

[3] https://github.com/anoopkunchukuttan/indic_nlp_library

[4] Due to limited availability of time, HAN for decoder side and HAN joint models were not used for experiments.

6 Summary

This paper presented the "FJWU_NUST" system submitted to the Similar Language Translation task at WMT20. The limited and out-of-domain parallel training data provided by organizers, emerged as a challenging task to train NMT models, whose quality is dependent on large data.

We have utilized monolingual data with back-translation along with available parallel data for training NMT system which incorporated context-aware HANs on encoder side. Our document-level systems outperformed sentence-level NMT systems, even in the absence of document-level corpora. This showed that document-level machine translation can be reasonable alternative of NMT, since it can deliver good quality translation for low-resource languages without requiring document-level parallel data.

Multilingual Neural Machine Translation: Case-study for Catalan, Spanish and Portuguese Romance Languages

Pere Vergés Boncompte and Marta R. Costa-jussà
TALP Research Center
Universitat Politècnica de Catalunya, Barcelona
pere.verges@est.fib.upc.edu, marta.ruiz@upc.edu

Abstract

In this paper, we describe the TALP-UPC participation in the WMT Similar Language Translation task between Catalan, Spanish, and Portuguese, all of them, Romance languages. We made use of different techniques to improve the translation between these languages. The multilingual shared encoder/decoder has been used for all of them. Additionally, we applied back-translation to take advantage of the monolingual data. Finally, we have applied fine-tuning to improve the in-domain data. Each of these techniques brings improvements over the previous one.

In the official evaluation, our system was ranked 1st in the Portuguese-to-Spanish direction, 2nd in the opposite direction, and 3rd in the Catalan-Spanish pair.

1 Introduction

Research in the field of Machine Translation (MT) has been growing during these last years. From statistical approaches (Koehn et al., 2003) to neural ones (Bahdanau et al., 2015), the progress has been impressive. Even after having achieved exceptional results based only on attention mechanisms (Vaswani et al., 2017), there are still many challenges and improvements remaining, for instance, multilingual translation from languages other than English, which have lower resources, and domain adaptation.

In order to tackle these challenges, the Similar Language Task organized in the context of the Conference on Machine Translation (WMT 2020) has provided an appropriate setting for them. Within this task, the focus is the translation between languages that are different from English, and more specifically, the focus consists of translating languages that are from the same family. The families included are the following: South-Slavic, Indo-Aryan, and Romance.

In our case, we have devoted the research to Romance languages, which include Spanish, Portuguese, and Catalan. The evaluation comprised all translation directions, but only provided parallel training data for Spanish-Portuguese and Spanish-Catalan. We approached the Portuguese-Catalan pair both from a pivot-based and zero-shot perspective.

In this paper, we make use of the well-known multilingual shared encoder/decoder and we show its effectiveness when applied to languages of the same linguistic family. Additionally, we benefited from back-translation and fine-tuning.

2 Background

In this section, we show an overview of neural-based multilingual machine translation and domain adaptation using fine-tuning.

2.1 Multilingual translation

When having multiple languages, there is the opportunity to use several NMT architectures, based in the Transformer (Vaswani et al., 2017). Among the alternatives, we can share encoders and decoders (Johnson et al., 2017) or have specific encoders and decoders for each language (Escolano et al., 2020). In this paper, we are using the shared approach and we are leaving as further work to compare with other ones.

Shared encoder-decoder One direct approach is using a single encoder/decoder shared for all languages (Johnson et al., 2017). In this case, parameters and vocabulary are shared among all language pairs and it helps the generalization across languages improving the translation for the low resource language pairs (Aharoni et al., 2019). Additionally, the shared encoder/decoder allows using zero-shot easily, only by adding a tag in the source sentence. The source sentence has to contain the

Proceedings of the 5th Conference on Machine Translation (WMT), pages 447–450

language abbreviation of the target language. So, when translating from Catalan to Spanish, we have to include the *<2es>* tag at the beginning of the Catalan source sentence, which means that we are translating into Spanish.

```
<2es> Bon dia -> Buenos días
```

Therefore, it is necessary to add the tag to indicate the target language, followed by the sentence to be translated. This is necessary both in training and inference.

2.2 Monolingual corpus selection for back-translation

There is a large amount of monolingual data available for this task. Monolingual data can improve the system by using back-translation (Sennrich et al., 2016). However, back-translation is a process that consumes a lot of resources, so we decided to select the monolingual data within the target domain. The selection criterion has been the TF-IDF (Term Frequency – Inverse Document Frequency), which defines the relevance of the words in a document. Using this criterion, we compared all the available monolingual data against the development set and only kept the files that had a higher score among all.

2.3 Domain adaptation

One approach to improve the translation of a specific language domain is to make use of fine-tuning techniques. Fine-tuning consists of retraining a model that has already been trained with out-of-domain data, with in-domain data. The disadvantage of fine-tuning is that it tends to overfit, due to the small amount of in-domain data used, compared to the out-of-domain data. Sometimes the final model might fall into the problem of catastrophic forgetting (French, 1999).

One approach to avoid over-fitting and catastrophic forgetting is to do mixed fine-tuning, which consists of shuffling the in-domain with the out-of-domain data, and then train normally on this combined data (Chu and Dabre, 2019).

3 Experimental Framework

In this section, we describe the datasets used for the task, the data preprocessing, the training, and the evaluation of the bilingual and multilingual systems.

3.1 Data and Preprocessing

Data Selection All the data used in our experiments has been provided by the organizers, so we did not make use of any additional parallel nor monolingual data. For the Catalan-Spanish and Spanish-Portuguese translation, we used all the parallel data available, which is about 11.3 million sentences for the Catalan-Spanish translation and 4.1 million sentences for the Spanish-Portuguese. For the Catalan-Portuguese we did not have any parallel data. We have also used monolingual data for back-translation purposes. Two million sentences have been used from the *CaWaC* file for Catalan, about 1.1 million sentences from *News-commentary-v15* and *News-crawl-2019* files for Portuguese, and 1.5 million sentences from *News-commentary-v15* and *News-crawl-2015* for Spanish. The multilingual model has been trained using all the parallel data, and with pseudo-parallel data that has been obtained by applying back-translation. To achieve the back-translation we used our best system at the moment to perform the translation of the monolingual data, obtaining the pseudo-parallel corpus. As said in Section 2.2, the monolingual data has been selected using TF-IDF as the measure for text similarity [1]. We used 2/3 of the development set for fine-tuning purposes and 1/3 of the development set as a test set.

Preprocessing We followed the standard procedure for preparing the data, which consists of normalizing, tokenizing, truecasing, and cleaning (limiting sentences from 1 to 50 words). To perform these actions we made use of the *Moses*[2] scripts. We extracted the joint subwords with byte-pair encoding (BPE)[3].

3.2 Parameter Details

The bilingual and multilingual models are both based on the Transformer architecture, implemented with *fairseq* toolkit [4]. We assigned six attention layers for the encoder and the decoder, each having four attention heads per layer, with an embedding dimension of 512. Additionally, all the models shared the source and target embeddings. The multilingual model shared the embeddings among all language pairs. Each batch was

[1] https://github.com/BhargavaRamM/Document-Similarity

[2] https://github.com/moses-smt/mosesdecode

[3] https://github.com/rsennrich/subword-nmt

[4] https://github.com/pytorch/fairseq

assigned to have a maximum number of tokens of 2048. The optimizer used was Adam, setting the betas to β_1 = 0.9 and β_2 = 0.98, with a learning rate of 5e-4 varied with the inverse square root of the step number. The warm-up steps were set equal to 4000, a dropout of 0.1, and a weight decay and gradient clipping norm set to 0.

4 Results

The results show the improvements obtained by applying multilinguality, back-translation, and fine-tuning techniques. For the pair Catalan-Portuguese (CA-PT), in which there was no training data available. We have used the cascade technique, which consists of concatenating the translation of Catalan-to-Spanish and Spanish-to-Portuguese systems, and the other way around for the opposite direction. Also, we have used the multilingual system to obtain zero-shot translation for this pair.

ES→PT	27.20	27.62	28.80	29.55
PT→ES	29.70	30.57	30.89	32.12
CA→PT	20.99	24.94	25.52	26.94
PT→CA	25.21	28.00	27.97	29.18
CA→PT ZS	-	12.47	13.56	16.05
PT→CA ZS	-	17.67	19.64	19.56

Table 1: BLEU results for all the systems evaluated in the development of this study. BI = Bilingual, MULT = Multilingual, BACK = Multilingual with Backtranslation, FT = Multilingual with back-translation and Fine-tuning, ZS = zero-shot.

Table 1 shows that the multilingual model outperforms the bilingual model in all cases. Zero-shot performs worse than the cascade method. Applying back-translation to the multilingual model improves for most language pairs and directions. Finally, when applying fine-tuning to the back-translation model, we see an improvement in all pairs and directions, except for the PT→CA direction with zero-shot.

4.1 Official evaluation results

Here we report the official evaluation. We participated with our best system which was the multilingual model with back-translation and fine-tuning. For the CA-PT directions, we translated using the cascade technique, Table 2 reports the results on the evaluation test set. Our system was ranked 1st in the Portuguese-to-Spanish direction, 2nd in the opposite direction, and 3rd in the Catalan-Spanish pair. For the Catalan-Portuguese directions, the results were not released.

Directions	BLEU
ES-CA	60.50
CA-ES	68.84
ES-PT	32.33
PT-ES	33.82
CA-PT	32.80
PT-CA	34.40

Table 2: Official BLEU scores for the evaluation of the final test set.

5 Discussion

We will now discuss the results obtained for each system we have trained, comparing one against the others.

Bilingual model compared to the Multilingual model We have shown that the multilingual model outperforms the bilingual model in all translations directions, with an improvement that varies from +0.4 to +6.9 BLEU. The multilingual model allows for a better generalization by sharing the vocabulary among all the languages. Additionally, the multilingual model allows for zero-shot translation.

Back-translation This technique allows us to make use of monolingual data. The improvement with this technique varies from +0.5 to +3.4 BLEU, except when using the monolingual Catalan data (ES→CA and PT→CA directions). This deterioration is probably due to the lower resemblance (estimated using the TF-IDF score) of the *CaWaC* dataset compared to the target domain.

Fine-tuning We have applied fine-tuning to perform the domain adaptation. To do so, we added 2/3 of the development data set to the already trained model, which is the multilingual model with back-translation, since it was the best model we had so far. After doing so, we had to retrain the model from the last checkpoint, preventing it from overfitting. By applying fine-tuning, we were able to achieve improvements between +0.6 and +2.5 BLEU points (except in zero-shot). This fine-tuning improvement is achieved by using very few resources (1500 sentences) and less time compared to back-translation, which requires more resources and time.

6 Conclusion

We have observed how using a multilingual shared encoder/decoder in languages from the same family improves bilingual translation. This is due to a positive transfer among these languages while sharing vocabulary and embeddings. Additionally, this multilingual shared system has been improved with both back-translation and fine-tuning methods.

Acknowledgments

We are grateful to Carlos Escolano for his comments, corrections, and help throughout the investigations. Abstract

In this paper, we describe our submissions for Similar Language Translation Shared Task 2020. We built 12 systems in each direction for Hindi $\Longleftrightarrow$ Marathi language pair. This paper outlines initial baseline experiments with various tokenization schemes to train statistical models. Using optimal tokenization scheme among these we created synthetic source side text with back translation. And prune synthetic text with language model scores. This synthetic data was then used along with training data in various settings to build translation models. We also report configuration of the submitted systems and results produced by them.

1 Introduction

Machine Translation systems are models which aim to translate text from one language into another. There are multiple ways of building such a model (Rule Based, Data driven, Hybrid etc.). In this system description paper, we use data driven techniques to build MT systems. As the name suggests, data driven MT systems make use of parallel sentences (i.e. x^{th} sentence in two languages have same meaning). We make use of statistical (Koehn et al., 2003) and neural (Bahdanau et al., 2014) methods to build systems for Hindi Marathi pair.

Hindi Marathi language pair comes under purview of similar languages. Similar Languages are languages which exhibit lexical and structural similarities (Kunchukuttan et al., 2014a). This can be due to common ancestry or being in close proximity for long time. In current digital age communication, translation between similar language is a justifiable requirement. But there is a scarcity of good quality bitext for many language pairs, as is the case of Hindi Marathi. Hence, we used characteristics displayed by similar languages (in this case Hindi and Marathi) like similar form of spelling, pronunciation etc. Following Kunchukuttan and Bhattacharyya (2017) and Kunchukuttan et al. (2014b) we made use of byte pair encoding (Sennrich et al., 2016b) and morfessor toolkit (Virpioja et al., 2013) respectively as part of preprocessing step before training. Using cues from Koehn and Knowles (2017) and looking at the size of training data provided, we use statistical method to build initial models. To further salvage similarity between this language pair we made use of backtranslation (Sennrich et al., 2016a) to generate more synthetic data for further training using both neural and statistical methods.

For this shared task we developed 12 translation systems in each direction (Hindi $\Longleftrightarrow$ Marathi). To rank systems, we went through some test instances subjectively and also compared our BLEU scores with another Translation system. And chose top 2 systems in both direction using both subjective examination and detoknized BLEU scores. Subsequent sections give more detailed overview of systems developed.

2 Seed MT systems using different tokenization schemes

Experiments in Koehn and Knowles (2017) show that Statistical Machine Translation model fairs better when compared to Neural model in case of low resource setting. So, we make use of SMT model to make initial baseline systems using various tokenization schemes. We use these systems as seed system, used to create synthetic dataset for further training by back translation.

2.1 Data

For our initial experiments we just used parallel and monolingual corpora shared by the organizers. We include training data to monolingual corpus for each language (LM corpus) to make language model. Parallel text consisted of bitext from 3

Proceedings of the 5th Conference on Machine Translation (WMT), pages 451–455

Corpus/Language	Hindi				Marathi			
#of Tokens	basicTok	BPE	Morf	#of Sentences	basicTok	BPE	Morf	#of Sentences
Train	840863	977742	38246	38246	638467	867968	851394	38246
Dev	32106	36482	34600	1411	25552	33997	33828	1411
Monolingual	1455510657	1760885875	1629220967	77722389	4834280	6715047	6526439	369403

Table 1: Total number of Tokens in each file after various tokenization schemes, last sub-column in both languages column denotes total number of lines in respective corpus

sources namely *News*, *PM India*, *Indic WordNet*. *Indic Wordnet* is not used in training because we found multiple instances of sentence pairs in which one of the sentence was incomplete.

2.2 Preprocessing

We used the IndicNLP toolkit[1] to tokenize all corpora as first preprocessing step. Then we made use of a BPE (Sennrich et al., 2016b) model trained with 10000 merge operations on the LM corpus for both Hindi and Marathi. The resultant model was used to tokenize words to subwords in sentences for all texts. Morfessor (Virpioja et al., 2013) was also used as another alternative preprocessing step. We trained a morfessor model on the full LM corpus of Marathi and an equally sized Hindi Corpus. And taking cue from IndicNLP toolkit, we used '+' as delimiter when segmenting words into segments i.e. a word *xyz* which was to segment as *x yz* will segment as *x+ yz*. Table 1 shows statistics of preprocessed data. We used all possible combinations of tokenization schemes while training initial models, these tokenization schemes were,

- Basic tokenization denoted as BasicTok in Table 1 which make use of IndicNLP toolkit.
- BPE which tokenize words into subword and is denoted as BPE.
- Tokenization using Morfessor, which is denoted as Morfes.

2.3 Machine Translation Model

We made use of Moses toolkit (Koehn et al., 2007) to build statistical models trained with tokenized bitext. We also use GIZA++ (Och and Ney, 2003) to find alignments between parallel text and grow-diag-final-and method (Koehn et al., 2003) to extract aligned phrases. And utilize KenLM (Heafield, 2011) to train a trigram model with kneser ney smoothing on monolingual corpus of both languages. MERT (Och, 2003) is used for tuning the trained models. We evaluated these models on dev set. Results are given in Table 2.

2.4 Using back-translation to augment training data

Based on the results in Table 2 we make use of following tokenization schemes depending on direction of translation,

- BPE as tokenization preprocessing scheme on both languages when translation direction is from Hindi to Marathi.
- Morf as tokenization scheme for Marathi and Basic tokenization for Hindi when translating from Marathi to Hindi.

After translating monolingual corpus, we did the following post processing based on direction of translation,

- In case of Marathi to Hindi translation, in post processing we remove '+' delimiter. This is due to Marathi being morphological richer than Hindi.
- For Hindi to Marathi,we simply joined the subwords in text translated.

Due to time constraint we translated some part of Hindi monolingual corpus (Authentic$_{Hindi}$) to Marathi (Synthetic$_{Marathi}$). We used beam search with default setting in Moses for this translation. We used already trained LM from Section 2.3 to learn average LM score of BPE tokenized Marathi monolingual corpus. Synthetic$_{Marathi}$ is than pruned (SyntheticPruned$_{Marathi}$) by keeping back-translated sentences which have LM score higher then average LM score on aforementioned Corpus. Same process is followed while translating Authentic$_{Marathi}$ to Synthetic$_{Hindi}$ and further pruning to get SyntheticPruned$_{Hindi}$. Statistics related to back-translated data and resultant pruned corpus is given in Table 3.

Back Translation direction L1 to L2	Hindi to Marathi	Marathi to Hindi
Sentences translated	456106	369403
Average KenLM Score of Monolingual data in L2	62.66	42.25
Sentences which are above this LM score	283043 (62.05%)	215417 (58.31%)
Average Sentence length of pruned corpus with standard deviation	10.25, 4.80	11.57, 4.52

Table 3: Statistics of back translated data

3 MT models using augmented bitext

For augmented data experiments we had following datasets available for training,

- Original training text
- Synthetic Marathi and Authentic Hindi
- Synthetic Pruned Marathi and Authentic Pruned Hindi
- Synthetic Hindi and Authentic Marathi
- Synthetic Pruned Hindi and Authentic Pruned Marathi

We ran experiments on following dataset combinations, for Hindi to Marathi Systems with BPE tokenization on both Hindi and Marathi,

1. Original training text + Synthetic Marathi and Authentic Hindi + Synthetic Hindi and Authentic Marathi
2. Original training text + Synthetic Pruned Marathi and Authentic Pruned Hindi + Synthetic Pruned Hindi and Authentic Pruned Marathi
3. Original training text + Synthetic Hindi and Authentic Marathi
4. Original training text + Synthetic Pruned Hindi and Authentic Pruned Marathi

And for Marathi to Hindi System, we ran following dataset combinations with morfessor model tokenization on Marathi and Basic Tokenization on Hindi,

1. Original training text + Synthetic Hindi and Authentic Marathi + Synthetic Marathi and Authentic Hindi
2. Original training text + Synthetic Pruned Hindi and Authentic Pruned Marathi + Synthetic Pruned Marathi and Authentic Pruned Hindi
3. Original training text + Synthetic Marathi and Authentic Hindi
4. Original training text + Synthetic Pruned Marathi and Authentic Pruned Hindi

All these dataset combinations were used to train following methods to build MT models with respective default configurations available in respective toolkits,

- SMT model using Moses toolkit (Koehn et al., 2007)
- NMT model with attention using Opennmt toolkit (Klein et al., 2017)
- NMT model with attention and copy attention (See et al., 2017) using Opennmt toolkit, to make use of similarity between Hindi Marathi language pair

4 Result

To submit two best systems out of 12 in each direction as directed by shared task, we did two evaluations. Firstly, we compared our system outputs to output of another publicly available translation model. Second, we went through some random outputs of all system outputs. We found that in most systems synthetic-authentic dataset which was not pruned with LM scores along with original training set performed better than pruned augmented bitext and original corpus. Following this, we selected following system outputs as our submission,

- Hindi to Marathi System:
  - Primary Submission: NMT with Attention + Original parallel text + SyntheticHindi_AuthenticMarathi
  - Contrastive Submission: NMT with Attention and CopyAttention + Original parallel text + SyntheticMarathi_AuthenticHindi + SyntheticHindi_AuthenticMarathi
- Marathi to Hindi System:
  - Primary Submission: NMT with Attention + Original parallel text + SyntheticMarathi_AuthenticHindi + SyntheticHindi_AuthenticMarathi
  - Contrastive Submission: SMT + Original parallel text + SyntheticMarathi_AuthenticHindi + SyntheticHindi_AuthenticMarathi

Table 4 gives the scores we received for these systems.

Language Direction	Submission Type	BLEU	RIBES	TER
Hindi to Marathi	Primary	11.41	57.2	79.96
Hindi to Marathi	Contrastive	10.21	55.17	82.01
Marathi to Hindi	Primary	18.32	59.31	77.35
Marathi to Hindi	Contrastive	21.11	60.76	77.28

Table 4: Scores for our systems

Both of our Hindi to Marathi Systems were somewhere in the middle compared to the other submissions. On the other hand Marathi to Hindi Contrastive submission (which was trained using SMT) was in top 5 standings.

Abstract

This paper describes the University of Maryland's submissions to the WMT20 Shared Task on Chat Translation. We focus on translating agent-side utterances from English to German. We started from an off-the-shelf BPE-based standard transformer model trained with WMT17 news and fine-tuned it with the provided in-domain training data. In addition, we augment the training set with its best matches in the WMT19 news dataset. Our primary submission uses a standard Transformer, while our contrastive submissions use multi-encoder Transformers to attend to previous utterances. Our primary submission achieves 56.7 BLEU on the agent side (en→de), outperforming a baseline system provided by the task organizers by more than 13 BLEU points. Moreover, according to an evaluation on a set of carefully-designed examples, the multi-encoder architecture is able to generate more coherent translations.

1 Introduction

Recent advances have made MT a widespread tool for asynchronous consumption of text. The dream of dissolving language barriers, however, will not be fulfilled until MT enables two or more people carry on a synchronous conversation, each speaking their native languages. Building translation systems that enable seamless conversations between an English-speaking customer support agent and a German-speaking customer is the goal of WMT20's shared task of chat translation (Farajian et al., 2020). In participation of this shared task, we focused on the agent side, translating English utterances into German. Our methods are inspired by Voita et al. (2018) and Bawden et al. (2018), explicitly leveraging broader context to address coreference and cohesion to improve translation quality. We compare architectures of a standard transformer with a single encoder and a multi-encoder one with an additional transformer encoder to incorporate information from the previous utterance. In the case of blind testing or production use, since customer target utterances (English) will not be given, a separate de→en model was trained and used to back-translate customer utterances.

Additionally, given the limited training pairs, we experiment with augmenting our dataset. We selected a subset of WMT19 en-de news data that were similar to the chat training data, which we then added to the training data. The subset was constructed using a full-text search engine loaded with the entire en-de WMT19 news data, which iterated through each chat training example, querying for the two closest matches with both the source and target as search strings.

Our primary system, denoted `PRIMARY`, is a single-encoder pretrained transformer fine-tuned on WMT20 Chat data. The first contrastive system, denoted `CONTRASTIVE1`, is a multi-encoder transformer that pre-warms, using WMT19 news data, the weights of an additional encoder after loading the pretrained transformer. The second contrastive system, denoted `CONTRASTIVE2`, is a multi-encoder transformer that fine-tunes the pretrained transformer on a combination of WMT19 news data and WMT20 chat data.

2 Related Work

One of the main challenges for translating discourse arises from ambiguities of sentences when they are taken out of context, as MT models often do (Yamashita et al., 2009). Especially in dialogue, sentences tend to reference entities in previous sentences, which necessitates using cross-sentential information to translate a given sentence. Individual words can be translated in different ways,

*Equal contribution.

Proceedings of the 5th Conference on Machine Translation (WMT), pages 456–461
Online, November 19–20, 2020.

significantly varying the meaning of the resulting sentence in a larger context (Gao et al., 2015). In addition, dialogue in the customer support domain is a distinctive and spontaneous category of text, with colloquialisms, errors and minimal revisions. All of these deviations can accumulate error throughout the course of a conversation.

Dialogue Translation: Specific interests in translating dialogues can be found as early as Lee and Kim (1997)'s work on Korean-English dialogue translation based on syntactic patterns and *n*-grams. Though their model parses sentences into speech acts instead of generating full-sentence translations, they have pointed out the importance of context (previous sentence) in interpreting the current sentence properly. The most relevant recent work is (Maruf et al., 2018), in which contexts for both source-side and target-side are utilized as additional generation conditions for the decoder in their NMT model. Several variants of the model architecture and the attention mechanism are explored. However, their experiments are conducted on Europarl and OpenSubtitles. The former is formal language and the latter scripted conversations of movies and TV. Here, in contrast, chat data is informal unscripted real-world language.

Context-Aware Machine Translation: Chat translation can be regarded as a special case of context-aware translation. Jean et al. (2017) extends the vanilla attention-based neural MT model (Bahdanau et al., 2015) by conditioning the decoder on the previous sentence via attention over its words. Wang et al. (2017) propose a cross-sentence context-aware model. They integrate the historical representation into NMT with two strategies: a warm-start of encoder and decoder states, and an auxiliary context source for updating decoder. Bawden et al. (2018) use multi-encoder NMT models to exploit context from the previous source and target sentence. Voita et al. (2018) propose a context-aware model based on the Transformer. Their model controls the flow of information from the extended context and improves on pronoun translation.

NMT Facilitated with Retrieved Translations: There is a line of NMT research inspired by example-based translation systems that aims to generate better translations by retrieving and referencing additional translation pairs. Gu et al. (2018) utilize an off-the-shelf search engine to retrieve training sentence pairs whose source side is similar to a given source sentence and incorporate them as additional input to the decoder. Zhang et al. (2018) use the retrieved examples at prediction time to upweight outputs whose constituents match retrieved *n*-gram translation candidates. In a similar vein, but at training time rather than prediction time, we use a retrieval system to select similar examples from a larger dataset to augment the smaller in-domain training set.

3 Data Preparation

3.1 Preprocessing

We used the Moses toolkit (Koehn et al., 2007) to preprocess our data. The training corpus was tokenized and cleaned. After that, we applied byte pair encoding (BPE) (Sennrich et al., 2016) on the data with the BPE model learned on the data of the pretrained model (Section 4.1.1). Following the pre-trained model, we use its shared vocabulary for both target and source sides. The size of the vocabulary, which is the union of English and German tokens, is 36,628.

3.2 Retrieval-Based Training Data Augmentation

There were only 13.85k utterances in the provided parallel WMT20 Chat training data. Given the limited data, we start off with a model pretrained on the WMT17 en-de news data, and additionally augment our training data with a filtered set of 4.75k lines of WMT19 en-de news data. We adopted Elasticsearch[1] to build a fast full-text search engine on the entire WMT19 en-de news set, and then iterated through each (source, reference) pair in the Chat training data. With each pair, we used the search engine to find the top two matches with the current source and target as search strings. We truncated this set to 4.75k training samples to limit the possibility of overwhelming our fine-tuning set and denote it *Chat-Similar News*. This technique brings the total training set to 18.6K parallel utterances.

4 Experiments

We conducted varied experiments in the English-German direction. We included the English reference of the customer utterances as training data for the scope of these experiments, even though this would not be available in a production setting. This was a strategy to provide more training pairs to our

[1] https://www.elastic.co/

models, knowing that the English references for customers is natural language, according to task organizers.

4.1 Systems Overview

We base all our systems off the Transformer architecture. Our implementation is based on the JoeyNMT toolkit (**?**). We kept hyperparameters common throughout. We experimented with the following settings:

1. Trained a standard single-encoder Transformer model.

2. Introduced a second encoder into our NMT architecture to process the preceding sentence, using context-target attention along with source-target attention to compute the final encoder hidden state, on a combination of *Chat-Similar News* and Chat.

3. As in item 2, introduced a second encoder and pre-warmed that encoder's weights on *Chat-Similar News*, before fine-tuning on Chat.

4.1.1 Off-the-shelf Pretrained Model

We found that an existing model trained on a different domain can generalize to this smaller dataset. We downloaded model weights for WMT17 en-de, provided by JoeyNMT Transformer[2]. This model was able to adapt to the chat domain, so the pretrained model was used for all experimental settings.

4.1.2 Common Hyperparameters

We kept hyperparameters consistent across models we tested, with some exceptions to account for slight differences in architecture. All models had embedding and hidden layers with 512 units, and feed-forward layers with 2048 units. A dropout rate of 0.1 was used on both the encoder and decoder layers. Training was performed with the Adam optimizer and in minibatches of 2048 tokens, with cross-entropy loss, an initial learning rate of 0.0002, and a patience of 8 validation cycles. All models were trained for a maximum of 65 epochs. The checkpoint with lowest validation perplexity is selected as the final model. For all validation cycles, greedy decoding is adopted. For testing, we used beam search decoding with a beam width of 5.

4.2 Single-encoder Implementation: `PRIMARY`

We trained a discourse-agnostic Transformer model with self-attention. This model had 6 layers for the both the encoder and decoder, each with 8 attention heads. A single-encoder implementation fine-tuned only on the Chat data was used to produce the primary submission results. We selected this model due to its slightly higher Chat validation BLEU (Table 1). It also achieves the highest test BLEU but with only minor differences with the contrastive systems. However, the gaps between it and the two contrastive multi-encoder implementations are not wide as can be seen.

4.3 Multi-encoder Implementation

Two context-aware models that are partial extensions of that described in Voita et al. (2018) were produced for the contrastive submissions. Voita et al. (2018)'s context-aware model encodes a source sentence and a context sentence independently and applies a gating function to produce a context-aware representation of the source sentence. We explored this combination idea by implementing a trainable gating function, *à la* (Voita et al., 2018), that takes the independently encoded source-side context and independently encoded source-side sentence as inputs to generate a representation for the decoder. Each layer retained 8 attention heads. We used 6 layers in each encoder. The total number of trainable parameters can be seen in Table 2.

4.3.1 Incremental Domain Adaptation: `CONTRASTIVE1`

This system has two steps: we pre-warm the context encoder of a multi-encoder implementation by fine-tuning on *Chat-Similar News* and validating on a subset of the Chat training data. We then fine-tune this intermediate model on the Chat training data, validating against Chat validation data. We consider this an incremental domain adaptation technique because we prewarm the trainable parameters of a new encoder with similar data, before finally tuning on the Chat data. Compared to a multi-encoder baseline implementation trained strictly on Chat, we achieve a 1.79 validation BLEU point improvement. Compared to `CONTRASTIVE2`, a model that fine-tunes on a mixture of Chat and *Chat-Similar News* in one step, we achieve a 0.59 validation BLEU point improvement.

System	Architecture	Domain Adaptation	Dev. BLEU	Test BLEU	Human Score
BASELINE	Standard Transformer	Chat	-	43.4	-
PRIMARY	Standard Transformer	Chat	**58.54**	56.7	79.29
Vanilla Chat	Multi-encoder	Chat	57.52	-	-
CONTRASTIVE1	Multi-encoder	Similar News → Chat	58.31	55.6	-
CONTRASTIVE2	Multi-encoder	Chat + Similar News	57.72	56.4	-
WMT20-CHAT-BEST	-	-	-	**60.1**	**88.21**

Table 1: Agent-side (en→de) performance of submitted systems on the official development and test sets of the WMT20 chat translation task. BASELINE was the best performing model in the WMT19 News task, PRIMARY is our primary submission, and WMT20-CHAT-BEST produced the best Agent-side outputs, according to human evaluation.

Model	# Params	# Samples
PRIMARY	63M	13845
CONTRASTIVE1	83M	(1303, 13845)
CONTRASTIVE2	83M	18624

Table 2: # Trainable parameters and # Training samples per model. Values within tuples indicate the number of training samples available to a corresponding, intermediate model.

4.3.2 Same-time Training of Chat-Similar News: CONTRASTIVE2

This system fine-tunes on the multi-encoder architecture with the combined *Chat-Similar News* and Chat training data in one shot. We see only a 0.2 validation BLEU point improvement here over the multi-encoder fine-tuned only with Chat (Vanilla Chat in Table 1).

5 Evaluation

5.1 Official Evaluation

BLEU scores on the development and test sets, and official human evaluation results are shown in Table 1. The PRIMARY system achieves the best validation and test BLEU. While CONTRASTIVE1 has a slightly higher validation BLEU, it turns out that CONTRASTIVE2 performs better at test time, showing that the same-time training technique may be less prone to overfitting.

5.2 Coherence Evaluation with Hand-crafted Examples

The official evaluation results seem to suggest the context-aware multi-encoder architecture (contrastive systems) is not superior to the standard Transformer which has no access to contextual information. We manually examined the training data, and noted that between two people interacting with each other on the phone or through their computer screens, there are not many indirect pronouns, possibly because there is no associated real-life gesturing necessitating expressions such as "that one" or "those ones". Seemingly, in the provided datasets, the need to be clear over the phone/internet means key words are often repeated for clarity, **especially** on the agent side ("I would like to order a pizza"; **"how can I help you with ordering a pizza"**). Inspired by (Bawden et al., 2018), we carefully evaluate performance of the systems on a hand-crafted dataset consisting of coreference and cohesion test instances. Example instances can be seen in Tables 4 and 5 respectively.

A contributor fluent in both English and German produced two versions of a dataset of 103 source-target pairs[3] based loosely off the provided validation set, following the spirit of (Bawden et al., 2018), in which a current utterance will require the previous utterance in order to make a disambiguating translation in the current. One version has the reference translation set to the correct coreference or cohesion resolution, while the other version can be a potentially correct translation viewing the source sentence in isolation but is incorrect with the additional context. The source side remains unchanged in both versions. We benchmarked each of our submitted models by producing hypotheses using each model given the source sentence, and then computing BLEU scores on the reference from both versions of this dataset.

In Table 3, we show the results of each model against the two versions. We used greedy decoding to generate the hypotheses. We observe that the contrastive multi-encoder systems, though performing worse in BLEU than the single-encoder primary system on the provided validation dataset, actually score higher in the specifically crafted correct coreference/cohesion dataset. By contrast, PRIMARY scores higher for the incorrect coreference/cohesion dataset. Furthermore, the difference in BLEU points between the correct and incorrect

[3] https://github.com/SongChujun/joeynmt/blob/master/chatnmt/coher/manual_coher.json

System	BLEU with Correct Ref.	BLEU with Incorrect Ref.	Diff
PRIMARY	50.44	**49.54**	-0.90
CONTRASTIVE1	50.64	48.84	-1.80
CONTRASTIVE2	**51.39**	49.23	-2.16

Table 3: Agent-side (en→de) performance of submitted systems on our coherence dataset.

Context utterance	Nein. Ich weiss nicht wo **sie** ist. (*No, I do not know where it is.*)
Source utterance	It's 200 meters north of City Center.
Correct reference	**Sie** ist zweihundert Meter nordlich vom Stadtzentrum.
Incorrect reference	**Es** ist zweihundert Meter nordlich vom Stadtzentrum.

Table 4: Example of sentence requiring anaphoric pronoun resolution. A better translation should bias to the correct pronoun based on context as 'sie' and not as 'er' or 'es' (for masculine and neuter nouns respectively).

Context utterance	Ist 30% in Ordnung als Trinkgeld? (*Is 30% alright as tip?*)
Source utterance	Yes, that's more than **generous**.
Correct reference	Ja, das ist mehr als **grosszuegig**.
Incorrect reference	Ja, das ist mehr als **wohlwollend**.

Table 5: Example of sentence requiring lexical disambiguation. Given the context of giving a "tip", a system should bias the translation of "generous" more towards "grosszuegig" (someone is free with money) and away from "wohlwollend" (more in the altruistic, do-gooder sense), which is inappropriate here.

coherence datasets is more significant in the contrastive systems, suggesting that the contrastive models are recovering more of the correct coreference and cohesion, as opposed to retrieving vocabulary words in other areas of the reference.

6 Discussion

Our results largely agree with those of (Voita et al., 2018), chiefly that combining knowledge from a previous "context" sentence can improve the model's ability to improve translation quality when measured against sentences whose translations require anaphora considerations. To accommodate this, we produced one set of sentences which require coreference and cohesion resolution, and one set of sentences that have invalid resolution. We found that each submitted system scored worse on the invalid set compared to the valid set, but the difference was more staggering (Table 3) in the context-aware contrastive systems, lending evidence that these models are able to resolve this type of anaphora.

Our work and submission to the shared task can be viewed with several caveats in mind, which may explain the sub-optimal performance of the contrastive systems compared to the primary system. First, we used hyperparameters consistent with a context-agnostic pretrained model in order to have a fair comparison for evaluation and because these presumably have been well-tuned *for the original model*. It may be the case that different hyperparameters would work better for this particular data and the slightly larger architectures used for the contrastive submissions. It would be worth strategizing with better hyperparameter optimization.

Secondly, we use the provided target sides of the de→en direction to provide context to our en-de data as if it were back-translated. Since both the agent and customer sides of this datasets were actually produced in English (the latter being translated with human-corrected machine translation), these additional utterances are likely higher quality than we would get from back-translating in a real test setting.

7 Conclusions

In this paper, we discussed our methods for training and submitting the outputs of three models for the WMT20 shared task of chat translation. Each system was based off a transformer model pretrained on WMT17 en-de news to provide better fluency. Our best system achieves a test BLEU of 56.7, improving over the provided baseline by more than 13 BLEU points, and less than 4 points behind the best shared task submission. Though we were unable to show that a context-aware model produced better translation quality than the context-agnostic model on the given dataset, our coherence evaluations indicated that it can produce better translations when measured against references needing context for

coreference and cohesion resolution. This was validated both in terms of BLEU and by model scoring of references.

Abstract

This paper describes Naver Labs Europe's participation in the Robustness, Chat, and Biomedical Translation tasks at WMT 2020. We propose a bidirectional German ↔ English model that is multi-domain, robust to noise, and which can translate entire documents (or bilingual dialogues) at once. We use the same ensemble of such models as our primary submission to all three tasks and achieve competitive results. We also experiment with language model pre-training techniques and evaluate their impact on robustness to noise and out-of-domain translation. For German, Spanish, Italian, and French to English translation in the Biomedical Task, we also submit our recently released multilingual *Covid19NMT* model.

1 Introduction

We participate in three German ↔ English tasks: Robustness, Chat, and Biomedical. Because these tasks allow the use of the same German-English data, we are able to submit a single model to all of them. We use adapter layers (Bapna and Firat, 2019) to specialize this common model on the provided in-domain data, and obtain a single multi-domain model.

1.1 Task description

Robustness Task This task is split into two tracks: 1) a *zero-shot* translation track whose goal is to make NMT models that are robust to unseen domains; 2) a *few-shot* translation track, where only a few thousand examples of a new domain will be provided as training data, to try to improve translation quality on this particular domain, while maintaining good quality on the other domains.

Chat Translation Task The goal of this task is to translate bilingual customer dialogues between two participants (one German-speaking "customer" and one English-speaking "agent") to the language of the other participant. It combines three challenges: document-level translation (of dialogues), domain adaptation, and noise robustness. Note that the data was originally all in English (even the customer side) and human-translated to German.

Biomedical Task This task is a typical domain adaptation task, where we have access to large amounts of generic parallel data, and smaller amounts of in-domain data. The provided test sets are at the document level, which may be useful to our document-level approach. While the data is clean, it contains many numbers, named entities, and compound medical terms, which may require some "robustness tricks" to handle properly.

Note that this task is very à propos, considering the current pandemic situation, in which a good-quality biomedical MT model could be very helpful for translating guidelines, news articles about COVID-19, or social media reactions. So, in addition to submitting our German ↔ English multi-domain model, we also participate in several language pairs (German, Spanish, Italian, and French to English) with our recently released multilingual *Covid19NMT* model (Bérard et al., 2020).[1]

1.2 Data

Table 1 describes the training data we used to train our models. The domain-specific training data (BConTrasT, Medline, and Robustness few-shot) was only used to fine-tune model instances for the relevant tasks. We filtered all the training data based on length (min 1 token, max 200, max ratio of 1.8), and automatic language identification with

*Work done during the author's internship at Naver Labs Europe

Proceedings of the 5th Conference on Machine Translation (WMT), pages 462–472
Online, November 19–20, 2020.

`langid.py` (Lui and Baldwin, 2012). We also removed duplicate sentence pairs.

We filtered the Medline training data to remove any sentence pair where either side (English or German) was in the Medline 2018 test sets so that we can use *Medline-test2018* for early stopping.

The *Covid19NMT* model (Bérard et al., 2020) used for our Spanish, Italian and French to English submissions to the Biomedical Task was trained on much larger amounts of training data, obtained from WMT and OPUS (Tiedemann, 2012).[2] It was trained in a multilingual way (many-to-one) with general-domain as well as biomedical data using domain tags (Kobus et al., 2017).

Table 2 describes the validation and test data we used. Some test sets, like *newstest2019* and *Medline-test2019* were only used for the final evaluation in this paper, while others (*BConTrasT-dev* and *Medline-test2018*) were also used for early stopping and model selection.

2 Our model

We explore several techniques to train a model that should be able to cover all tasks with minimal adaptation. We want our model to be bidirectional, robust to noise and new domains, and to be able to translate full bilingual documents at once.

2.1 Pre-processing

We normalize all whitespaces and apply Moses' `deescape-special-chars.perl` on the training data (Koehn et al., 2007).

We train a joint BPE model on the general-domain WMT20 parallel data (English plus German) with 24k merge operations and inline casing, which improves robustness to capitalized inputs (Bérard et al., 2019). We use an in-house BPE implementation similar to `SentencePiece` (Kudo and Richardson, 2018). Like the latter, it does Unicode NFKC normalization and pre-tokenizes its inputs based on their script. It also segments numbers and punctuation character-by-character. We only keep single characters in the dictionary whose count in the training data is greater than 1000. Rarer characters are replaced by a `<copy>` placeholder if they appear on both sides, and an `<unk>` token if they appear only on the source side. We drop them if they are on the target side only. At test time, we can decide whether an OOV character should be copied or ignored, by replacing it with `<copy>` or `<unk>`.[3] We choose to copy *unicode symbols* (including emojis and math symbols) and to ignore the other characters.

We start each source sentence with a source language tag and each target sentence with a target language tag. For documents, each sentence is prefixed with a language code, effectively acting as a sentence delimiter. In the Chat translation task, the language code is also an easy way for the model to detect the current speaker.[4]

[2] Contrary to the other tasks, the Biomedical Task puts no constraint on the training data used.

[3] Copy is followed by a post-processing step, where we replace target-side `<copy>` tokens by the source-side OOV symbols in the same order.

[4] Even though using these tags is not necessary for sentence-

We modified fairseq to load and pre-process its training data on the fly (normalization, BPE, tagging, synthetic noise, binarization, and batching). The advantage of this approach over the statically pre-processed training sets is that we can easily apply a different pre-processing at each epoch. This is useful for BPE dropout (where ideally, we'd like a different segmentation at each epoch) and for noise generation. We can also more easily sample from multiple corpora, and subsample from parallel documents or randomly create fake documents.

We train a sentence-level bidirectional model on the concatenated German → English and English → German parallel data (about 90M examples total), which we use as a baseline for the next steps.

2.2 Pre-trained encoder

Previous works (Edunov et al., 2019; Conneau and Lample, 2019; Clinchant et al., 2019; Lewis et al., 2020; Rothe et al., 2020) show that pre-trained LMs can improve performance of NMT models, especially in low-resource settings. Clinchant et al. (2019) show that, even though the benefit of pre-trained LM is less clear in high-resource settings, it can lead to better domain robustness. In this work, we explore this aspect further and experiment with several pre-trained models for encoder initialization. First, we train a Masked Language Model (MLM) that follows the same architecture as the NMT model's encoder. Since our encoder is bilingual (it encodes both English and German) we train the MLM on a concatenation of large monolingual English and German datasets (100M lines in total per language from news-crawl, news-discuss, and Common Crawl).

We also experiment with a large publicly available MLM model: RoBERTa Base,[5] and initialize our NMT encoder with this model's parameters. Then, we train all parameters further on the NMT task. Using an existing model saves us the cost of having to train a new model. But there are a few downsides: RoBERTa is English-only, so we cannot use it in a bidirectional setting. We are also constrained to use RoBERTa's tokenizer and vocabulary, which prevents us from sharing source and target embeddings. It also complicates custom source-side pre-processing techniques (e.g., inline casing). Our models initialized with RoBERTa have a separate target-side (German) vocabulary of size 24k. They do not use any of the tricks (no copy symbol, inline casing, back-translation, etc.)

Previous work (Voita et al., 2019; Tenney et al., 2019) suggests that the last layers of a pre-trained LM might not be useful for the final task. For this reason, we also try initializing the encoder with the first 8 (out of 12) layers from RoBERTa.

2.3 Tagged back-translation

We back-translate the German and English *news-crawl* monolingual corpora (see Table 1) using our bidirectional Transformer Big baseline with sampling (Edunov et al., 2018). Back-translation is done at the sentence level, but we reassemble the output sentences and their corresponding sources into pairs of documents for document-level training. Like Caswell et al. (2019); Bérard et al. (2019), we prefix the back-translated examples with `<BT>`.

We downsample from our training corpora so that an epoch always corresponds to roughly 90M samples[6] regardless of the presence of back-translation or document-level training; and so that real and back-translated data are approximately balanced. We also upsample the real document pairs by a factor of 100, as we expect them to be more valuable to document-level training than fake documents and back-translated ones.[7]

2.4 BPE dropout

Kudo (2018) propose "subword regularization", a non-deterministic tokenization algorithm, whose stochasticity level can be controlled thanks to a probability parameter. They show that using it to encode the training data acts as regularization and that it can improve translation quality for low-resource or out-of-domain translation. Provilkov et al. (2020) implement the same idea with the BPE algorithm, which they call "BPE dropout".

We apply BPE dropout over the source side of the training data with probability 0.1, as our early experiments with target-side BPE dropout gave worse results than regular BPE.

level models, we wanted our sentence-level and document-level models to share the same pre-processing so that we could easily combine them in ensembles if need be.

[5] https://github.com/pytorch/fairseq/tree/master/examples/roberta

[6] A "sample" being a sentence pair in sentence-level training, or a pair of documents (real, sub-sampled or fake) in document-level training.

[7] For instance, when training document-level bidirectional models with back-translation, an "epoch" consists in 41.7M pairs of fake documents, 42.5M pairs of back-translated documents, and 6M pairs of real documents.

2.5 Noise generation

To increase robustness to noise, we inject random synthetic noise on the source side of our training data (Belinkov and Bisk, 2018; Karpukhin et al., 2019; Vaibhav et al., 2019; Bérard et al., 2019). We modify each sentence with probability 0.1, and each character within this sentence with probability 0.1. Character modifications are either a deletion, a swap with the next character, a duplication, a substitution with a random candidate character, or a character insertion at the preceding position. Candidate characters are extracted from the model's German-English dictionary and sampled according to their rank in this dictionary using a Zipf distribution. Like for back-translation, we start each noised source sequence with a special `<noisy>` tag. Thanks to our on-the-fly pre-processing, we generate new noise at each epoch.

2.6 Document-level training

Like Junczys-Dowmunt (2019); Saleh et al. (2019) we train our models on parallel documents of size up to 1024 BPE tokens. Table 1 sums up the available parallel corpora with document boundaries. We use similar techniques as Junczys-Dowmunt (2019):

- All parallel documents are randomly subsampled into smaller documents (of consecutive sentences).
- The sentence-level parallel data (e.g., ParaCrawl) is also used and transformed into fake documents by randomly merging consecutive sentences.[8] The source side of these documents is prefixed with `<fake>`.

We also keep the same techniques as before: back-translation, BPE dropout, and noise. They just work on full documents instead. To deal with potentially noisy and bilingual documents, we also do the following:

- Each parallel document (including the fake ones) has a 0.2 probability of having all its source/target sentences randomly swapped. The goal is to have an MT model that can translate bilingual documents.
- We randomly drop each sentence delimiter on both the source and target side with probability 0.1. The goal is to force the model to rely exclusively on the source-side delimiters for generating output delimiters, and not on end-of-sentence punctuation. We hope that this will help generate documents of the same length as the input documents.

2.7 Domain adaptation

For domain adaptation, we test two settings: fine-tuning the entire model on the in-domain data (Freitag and Al-Onaizan, 2016), or adding domain-specific adapter layers which we train while freezing the other parameters (Bapna and Firat, 2019; Philip et al., 2020). While fine-tuning is often the optimal strategy, adapters can achieve close performance while significantly reducing the number of parameters per task: we can have a single model for all tasks, with a small set of additional parameters for each task.

We use adapters of size 64 and 1024 respectively for sentence-level and document-level models.[9] We found that the sentence-level models quickly overfit the in-domain data when trained with higher capacity adapters. When fine-tuning the whole model, we continue with the same learning rate schedule as the pre-trained model. When training adapters, we use a fixed learning rate of 10^{-4} and train on a single GPU without delayed updates.

For domain adaptation, we disable noise generation, BPE dropout, and fake documents. When possible, domain adaptation of the document-level models is done with document-level in-domain data. Early stopping is done according to document-level perplexity on the validation sets.

For the Chat Translation Task, we include the training data in both the forward and backward directions (i.e., target side as source and source side as target). We prefix backward sources with the `<BT>` tag. For the other tasks, we adapt the bidirectional models with the in-domain data in both directions if available (i.e., our adapters are bilingual).

3 Experiments

3.1 Evaluation settings

For all test and validation sets but *Medline-test2019*, we use *SacreBLEU* with the default settings against untokenized references.[10] When the

[8] Each sentence pair has a probability of 0.8 of being merged with the previous sentence pairs, with a max document size of 1024 tokens or 64 sentences.

[9] Our adapters use near-zero initialization and the original *pre-norm* architecture (Bapna and Firat, 2019), even though our Transformer models are post-norm.

[10] `BLEU+case.mixed+numrefs.1+smooth.exp+tok.13a+version.1.4.3`

test set is document-level, we split it into sentences first, as well as the model outputs and compute regular sentence-level corpus BLEU.

For *Medline-test2019* we use `SacreBLEU` in case insensitive mode with the `intl` tokenization,[11] which mimics closely the evaluation settings of the WMT19 Biomedical task. We use the alignments provided by the organizers, and keep all alignments regardless of their annotation (e.g., `OK` or `NO_ALIGNMENT`) but remove those where one side is marked as "omitted".

3.2 Hyper-parameters

We use the Transformer Big architecture (Vaswani et al., 2017) with post-norm (as prior experiments with pre-norm gave worst results), which we train with fairseq (Ott et al., 2019). We share the source and target embeddings and tie them with the vocabulary projection. We use Adam with warmup and a maximum learning rate of 0.001. Training is done on 4 GPUs with mixed precision and accumulated gradients over 16 updates (Ott et al., 2018). In some cases, we had to reduce the learning rate to 0.0005 because of exploding gradient issues. We use a dropout rate of 0.1 and label smoothing of 0.1. We train for maximum 24 epochs with early stopping according to BLEU on *newsvalid*.

The models using back-translation, BPE-dropout, and/or noise are initialized with the epoch 12 checkpoint of the baseline model and trained for 12 more epochs. The doc-level model is initialized from the sent-level model with *BT + BPE-dropout + noise*, and fine-tuned for 4 more epochs.

The pre-trained MLM is trained with RoBERTa Base's default training settings but uses the same architecture as the NMT encoder (sinusoidal positional embedding, post-norm Transformer). We also remove the non-linear transformation in RoBERTa's LM head. Due to time constraints, we train the MLM for 2 epochs only.

The models initialized with RoBERTa use the RoBERTa Base architecture for the encoder (embedding size of 768 and feed-forward size of 3072), and a Transformer Big with 3 layers only for the decoder. They also use a higher dropout rate of 0.3. As source-side pre-processing, we use the same GPT tokenizer as RoBERTa; and as target-side pre-processing, a monolingual SentencePiece model of size 24k without inline casing.

[11] `BLEU+case.lc+numrefs.1+smooth.exp+tok.intl+version.1.4.3`

3.3 Ensembles

As primary submissions to all three tasks, we use an ensemble of three document-level models. To save computation time, and avoid re-training new models, we ensemble models that were trained with different settings, but whose pre-processing is compatible (see Table 5). To achieve better ensemble results, we train three different instances of Bidirectional Big (for 12 epochs), which serve as initialization for models *8*, *9*, and *10* (fine-tuned for 12 more epochs). These three models are combined with model *7* as ensemble *15*. We continue training these three models with document-level data (for 4 epochs) to create ensemble *19*. Ensembles *18* and *22* are obtained by taking the same models as ensembles *15* and *19*, training domain-specific adapter layers, and combining them again.

3.4 Results

ID	Model	DE-EN	EN-DE
0	FAIR 2019 (single)	41.0	40.9
1	Monodirectional Base	40.7	41.1
2	Bidirectional Base	39.9	40.1
3	Monodirectional Big	**42.0**	41.6
4	Bidirectional Big	41.9	**41.8**

Table 3: Comparison of monodirectional versus bidirectional models. BLEU scores on *newstest2019*. Bidirectional Big serves as a baseline for our next experiments. *FAIR 2019 (single)* is one of the models from the ensemble that ranked first in the WMT19 News Task (Ng et al., 2019).

Baseline models We compare Transformer Base and Transformer Big architectures, and monodirectional (German → English and English → German) versus bidirectional models (German ↔ English). Table 3 shows their results on *newstest2019*.

Robustness to noise Table 4 evaluates the robustness of our models to several forms of synthetic noise and to other types of tokenization.[12] BPE dropout slightly improves robustness to certain types of synthetic noise, and drastically improves robustness to other types of tokenization, especially character-level translation ("spelled out" column). Source-side synthetic noise dramatically

[12] While robustness to tokenization is not necessary for these tasks, it can be a desirable property for an NMT model. For instance, we could reduce the size of the vocabulary for model compression, or change the tokenization algorithm and vocabulary for the model to be compatible with other models (e.g., for ensembling, pre-training, etc.)

ID	Model	Clean	Char noise	No space	No 'e'	Spelled out	Other BPE
0	FAIR 2019 (single)	41.3	15.0	6.2	17.5	–	–

11	10 + Docs	**42.4***	**33.6***	**23.3***	**33.8***	**34.6**	**39.4**

Table 4: Robustness on English-German translation (case-insensitive BLEU) to synthetic noise (random char-level noise, all whitespaces removed or all 'e' letters removed) or to different tokenizations (char-level instead of BPE, or different BPE model than used for training). All the test sets are variants of *newstest2019*. *Char noise* consists in modifying each character with 0.1 probability, with either a deletion, insertion (of an ASCII letter or digit), substitution or swap. *Spelled out* means that we segment the input character-by-character (e.g., `I like pizzas` → `i _ l i k e _ p i z z a s`). With *Other BPE*, we use a different BPE model (trained with SentencePiece on lowercased monolingual news data); and whenever a word piece is out-of-vocabulary, we segment it as characters (i.e., spelling out). Numbers with $\star$ are obtained with document-level translation.

improves robustness to the same type of character-level noise and to the absence of whitespaces or of the 'e' letter.[13] Interestingly, when combined with BPE dropout, it also further improves robustness to other types of tokenization.

Note that the document-level model with noise is even better with noise robustness. This is probably due to its longer training (which means that it has seen more noise).[14] The same model used in sentence-level decoding mode (scores not reported here) achieves similar improvements.

Domain robustness and domain adaptation Table 5 shows the BLEU scores of our models on test sets from multiple domains (News, IT, QED, Medline, Chat). We can assess the domain robustness of our non-adapted models for use in the zero-shot robustness task. It also shows the translation quality of the adapted models on the Biomedical and Chat tasks (on their respective dev sets).

In our case, contrary to what Kudo (2018); Provilkov et al. (2020) observed, subword regularization with BPE dropout brings no clear improvement to BLEU scores on any of the domains.

We see that fine-tuning performs often better than the adapter layers. Yet, because the difference is minor, we settle with adapters for our submissions as they allow us to train one multi-domain model that can be submitted to all three tasks. They also let us participate in the few-shot task with a model that is adapted to a new domain and does not degrade on other domains (which fine-tuning is known to do, because of catastrophic forgetting).

The scores from Tables 3, 4, and 5 are obtained after normalization of our model outputs with Moses' `normalize-punctuation.perl` (Koehn et al., 2007). However, our submissions do not use any punctuation normalization, except for the robustness task (see below).

Task results Table 6 presents the official BLEU results of our primary and contrastive submissions to the three tasks. We always used the same ensemble of document-level models with adapters (*22*) as primary submission, and single document-level model with adapters (*21*) as first contrastive submission. As second contrastive submission, we submitted different models depending on the task (see Table 6's caption): ensemble of RoBERTa-initialized models (*12*), ensemble of sentence-level model (*18*) or *Covid19NMT* model.

3.5 Robustness Task

For this task, we also train a bidirectional Japanese-English model with all the allowed parallel data from the News Task (15.9M lines pairs). We use the same techniques as with German-English: copy

[13] These are examples of perturbations that humans are able to deal with, but NMT models struggle with. For example, try: "Collagus from across th U, and byond, bring valuabl xprinc and skills that strngthn and improv th work of th halth srvic, and bnfit th patints and communitis w srv."

[14] It was trained for 4 more "epochs". But we define an epoch as a fixed number of training examples, which are much longer when we do document-level training ($\approx 5\times$ longer in terms of BPE tokens).

Table 5: Domain robustness and domain adaptation on English-German translation (case-sensitive BLEU except for Medline). *News*, *IT*, *QED* and *Medline* are respectively *newstest2019*, *IT-valid*, *QED-valid*, *Medline-test2019* from Table 2. *Chat* is the English-German subset of *BConTrasT-dev*, which contains only the agent's utterances. Numbers with ⋆ are obtained with document-level translation. For *Chat*, we translate the full bilingual dialogues (using both the agent and the customer utterances as context), then compute BLEU on the agent's part only. The models in bold were submitted to one or several tasks (see Table 6).

symbol, inline casing, source-side BPE dropout, and source-side noise. However, we do not train at the document-level, nor do language model pre-training, back-translation, or ensembles. To reduce the effect of the JESC data whose English side is in lowercase, we add source-side corpus tags (Bérard et al., 2019) for all corpora but ParaCrawl (we do not use any corpus tag at test time). We also pre-tokenize the Japanese training data with Kytea, like specified by the organizers.[15]

The test sets for this task are sentence-level. However, we observe that some of the test sets contain lines with several sentences, which causes our models to generate too short outputs. To solve this issue, we sentence-split the test sets (with Moses' `split-sentences.perl` for German and English and basic split for Japanese, which has non-ambiguous end-of-sentence punctuation). Sentences originating from the same line are translated as a document with our document-level models.

[15]With KyTea 0.4.7: `kytea -out tok -model share/kytea/model.bin`

We normalize the punctuation of our model outputs, using `normalize-punctuation.perl` for English, and replacing ASCII double quotes with German-style quotes in German outputs.

Final results are reported in Table 6. The robustness task has two test sets for German-English: *Set 1* (German ↔ English), which appears to be very noisy text extracted from an online forum; and *Set 3* (only German → English), which contains clean and short sentences. The few-shot task lets us use a small corpus (8503 sentence pairs) of the same domain as *Set 3* to try to improve German → English translation quality over *Set 3* while not degrading quality over *Set 1*. We simply take the same models that we submitted to the zero-shot task and train adapters with the German → English in-domain data. Then, when translating *Set 3*, we turn on the adapters and turn them off for *Set 1*.

3.6 Chat Translation Task

For the primary and first contrastive submission, we used our document-level models with chat-domain

Model	Chat		Biomedical		Robustness zero-shot			Few-shot	
					Set 1	Set 1	Set 3	Set 1	Set 3
	EN-DE	DE-EN	EN-DE	DE-EN	EN-DE	DE-EN	DE-EN	DE-EN	DE-EN
Best	**60.4**	**62.0**	**30.4**	**34.8**	**48.0**	**43.9**	**44.7**	?	?
Primary	60.1	61.0	29.6	**34.8**	42.2	43.4	44.0	43.4	**45.4**
Contr. 1	58.8	59.4	28.4	34.3	40.7	42.1	43.4	42.1	44.2
Contr. 2	**60.4**	61.6	**30.4**	34.1*	41.9†	43.5	**44.7**	**43.5**	44.7

Table 6: Results of the three tasks (BLEU scores): top result in each task and scores of our primary and contrastive submissions. We only report results on German $\leftrightarrow$ English. Please refer to the appendix for the results on the other languages. *Primary:* Ensemble of three document-level models with adapters (*22*). *Contrastive 1:* Single document-level model with adapters (*21*). *Contrastive 2:* Ensemble of four sentence-level models with adapters (*18*). †: Ensemble of two RoBERTa-initialized models (*12*). $\star$: *Covid19NMT* model with `<medical>` tag (Bérard et al., 2020). As the Robustness Task organizers did not communicate official results at the time of submission, the numbers reported here are those appearing on the submission website (OCELoT).

adapters (*22* and *21*) to translate the full bilingual dialogues at once. The BLEU scores reported in Table 6 are computed separately for the agent and customer's side of the dialogues. The second contrastive model is bidirectional and sentence-level (*18*), and used to translate the dialogues utterance by utterance (without extra context).

3.7 Biomedical Task

We had issues with document-level decoding output length on the Medline validation and test sets. The number of sentence delimiters in the output does not always match that of the source document, which makes regular BLEU evaluation impossible. We get between 10% and 20% output documents with the wrong length for German-English, and more than 50% for English-German. This length mismatch issue seems to be caused by domain adaptation,[16] as non-adapted models get a perfect length. On the Chat translation task, there is virtually no length mismatch, and up to 10% length mismatch on *newstest2019*, caused by source documents that are close to or above the 1024 tokens limit.

Whenever a length mismatch happens, we revert to sent-level decoding for this particular document. As our English-German submission to the Biomedical task, we used fully sent-level decoding outputs (by our doc-level models), as almost 100% of the document-level outputs had the wrong length.

Our *Covid19NMT* model (Bérard et al., 2020) ranked first in Spanish-English and Italian-English (50.6 and 42.5 BLEU) and lags behind with less than 1 BLEU difference in German-English and French-English (34.1 and 43.1 BLEU).

[16]One likely explanation is that there are some alignment errors in the Medline training data that cause adapted models to ignore the sentence delimiters in some cases. For instance, we observed that the titles are often misaligned (e.g., "INTRODUCTION").

4 Conclusion

We find that, if given enough capacity (e.g., Transformer Big), a single bidirectional model can give similar performance to mono-directional models of the same size.

Like showed by Bapna and Firat (2019), it is possible to perform lightweight domain adaptation using adapter layers, and achieve comparable performance to fine-tuning of the whole model. Thanks to adapter layers added to our bidirectional model, we achieve competitive results on all 3 tasks with one model.

MLM pre-training results for bidirectional models are inconclusive. The pre-trained model seems to be slightly more robust in some aspects, but not as robust to domain shift as one would hope. This may be due to fewer training epochs compared to our previous experiments (Clinchant et al., 2019). RoBERTa pre-training gives promising results in terms of noise robustness; it also seems to bring slight improvements in terms of domain robustness. Note that the models initialized with RoBERTa have fewer parameters than the Transformer Big NMT architecture.

Finally, document-level fine-tuning gives document-level decoding abilities to a bidirectional NMT model without degrading its sentence-level decoding performance. However, document-level decoding does not improve translation quality as measured by BLEU. We also find that generating documents with the right number of sentences (i.e., same length as the input) can be challenging on some test sets.

Abstract

This paper describes the joint submission of the University of Edinburgh and Uppsala University to the WMT'20 chat translation task for both language directions (English↔German). We use existing state-of-the-art machine translation models trained on news data and fine-tune them on in-domain and pseudo-in-domain web crawled data. We also experiment with (i) adaptation using speaker and domain tags and (ii) using different types and amounts of preceding context. We observe that contrarily to expectations, exploiting context degrades the results (and on analysis the data is not highly contextual). However using domain tags does improve scores according to the automatic evaluation. Our final primary systems use domain tags and are ensembles of 4 models, with noisy channel reranking of outputs. Our en-de system was ranked second in the shared task while our de-en system outperformed all the other systems.[1]

1 Introduction and challenges

The task's aim is to create machine translation (MT) systems to enable task-oriented communication between a service agent and a customer speaking different languages (English and German respectively). Like most dialogues, the texts can show strong context sensitivities, as the customer and the agent engage in a common activity and continually react to each other's utterances (Hardmeier, 2014; Bawden, 2018). However, the dialogues, which relate to ordering or reserving products and services from a limited set of providers, also follow fairly strong scripts and are anchored in a small discourse universe defined by the products on offer. Their context sensitivity is therefore counterbalanced by domain-specific conventions and expectations.

Our design choices are informed by an initial manual inspection of the training data and a baseline translation, which revealed that the main challenges relate to idiomaticity: incorrect or poor translation of English idioms, named entities and politeness markers (e.g. formal vs. informal forms of address, or poor translation of English *sir*) and an incorrect use of domain-specific terminology. Almost always, the problems were the result of an excessively literal translation of the source text, and this literalness also frequently affected the reference translations themselves too. Surprisingly, we found few instances of phenomena explicitly requiring context to be correctly translated (e.g. we did not find pronominal anaphora to be a major problem in the dialogues examined).[2] The context-dependent instances we did find were more task-specific (e.g. English *Enjoy!* should be translated differently depending on whether it is about a pizza (*Guten Appetit!*) or a film (*Viel Spaß!*)).

We therefore focus on domain adaptation and general context modelling strategies. Our submissions are based on existing state-of-the-art MT systems for news translation, which we fine-tune on in-domain and pseudo-in-domain data. We also experiment with (i) adapting the models to the different speaker roles and to the different tasks during fine-tuning and (ii) exploiting preceding context through a simple but effective method of concatenating previous sentences to the current one. Our code and models are publicly available.[3]

[1] http://www.statmt.org/wmt20/chat-task_results_DA.html

[2] We tested AllenNLP's coreference resolution tool (Gardner et al., 2018) on a few examples where pronoun resolution seemed relevant and found that it performed very poorly in these cases, confirming similar conclusions by Bawden (2016). We therefore decided not to model coreference explicitly.

Online, November 19–20, 2020.

2 Data

The task data consists of parallel task-oriented dialogues between an agent (English) and a customer (German) across six domains: (i) ordering pizza, (ii) making auto repair appointments, (iii) ordering a taxi, (iv) ordering movie tickets, (v) ordering coffee and (vi) making restaurant reservations. The dialogues were initially in English, retrieved from a subset of the TaskMaster-1 dataset (Byrne et al., 2019) and then manually translated into German at Unbabel.[4] Although the speaker tags are provided for each utterance, the conversations are not explicitly marked with their task domain. The task being to translate the agent's utterances from English into German and the customer's utterances from German to English, we evaluate each translation direction separately, using only the agent's utterances for en–de translation and the customer's utterances for de–en. For training however, we use the full set of 13,845 utterances for both directions.

3 Approaches

We explore four approaches, each of which is detailed below: (i) pretraining using additional data sources, (ii) speaker adaptation, (iii) domain adaptation and (iv) incorporating previous context.

Pretraining To account for the limited in-domain data, we use pre-existing MT models trained for the WMT'19 news task (Barrault et al., 2019) and then continue training on pseudo-in-domain web crawled data from the Paracrawl project[5] (Bañón et al., 2020), before fine-tuning on the in-domain chat training data. We compare two different base systems for each language direction: UEDIN models[6] ((Bawden et al., 2019a) and FAIR models (Ng et al., 2019). The pseudo-in-domain data on which training is continued is created by filtering Paracrawl data using dual conditional noisy cross-entropy filtering (Junczys-Dowmunt, 2018). This consists in training a neural language model for each language on the task training data, and jointly scoring each parallel sentence in Paracrawl using the two models. We take the top scoring 2.5 million subset of the original 34 million en–de sentences (those that most resemble the task data).

Speaker adaption Distinguishing between the two speaker roles is important as they have different contributions to the dialogue; the customer's utterances are short, interrogative and informal, while the agent's utterances are often long, informative and more formal. We adapt our models to each speaker by using the speaker identity (provided with the task data) as a pseudo-token (Sennrich et al., 2016a): we prepend a speaker tag to each utterance on both the source and the target side.

Domain adaptation Knowing which task the dialogue belongs to (e.g. pizza, film) can be important for disambiguation, as described in Section 1. Similarly to speaker adaptation, we adapt to the different tasks (i.e. domains) by prepending a domain tag to each utterance on both the source and target side. We also consider a setup where all the utterances are tagged with speaker and domain-tags (see the example in Table 1). The dataset consists of chats across six different domains (pizza, auto, taxi, movie, coffee, and restaurant). As the domains are not indicated in the task dataset, we obtain domain tags by automatically classifying each dialogue as belonging to one of the six tasks using the English side of the data and a baseline German translation.

The dialogue classifier is trained by unsupervised k-means clustering of the training set dialogues with scikit-learn (Pedregosa et al., 2011). As features, we use the nouns in the texts (as recognised by the SpaCy PoS tagger[7]), which works substantially better than using all words. The 6 clusters are initialised to the word sets {*pizza*}, {*auto, car, repair*}, {*ride*}, {*movie*}, {*coffee*}, {*dinner, restaurant*}. Dialogues in the test set are then assigned to the cluster with the nearest centroid. To evaluate the classifier, we manually annotated 49 dialogues from the training set. Training only on the remainder of the training data, we achieved perfect accuracy on the annotated set.

To simulate an online translation scenario, we also experimented with classification using only the initial utterances of each dialogue. In this setting, it was beneficial to project the feature space to a very low dimension using Latent Semantic Analysis (LSA). The best results with a macro-averaged F-score of 0.862 (precision 0.896; recall 0.867) were obtained by using the first 4 sentences and an LSA dimensionality of 5. However, since there was no online constraint in the shared task, we ultimately decided to use the more accurate

[6] Although the WMT'19 submission included only de–en, we also use the similarly trained model for en–de.

[7] https://spacy.io

Adaptation	Source text	Target text
Speaker	<speaker=customer> Perfect. Okay, got it.	<speaker=customer> Perfekt. In Ordnung, verstanden.
Domain	<taxi> Perfect. Okay, got it.	<taxi> Perfekt. In Ordnung, verstanden.
Speaker+domain	<taxi> <speaker=customer> Perfect. Okay, got it.	<taxi> <speaker=customer> Perfekt. In Ordnung, verstanden.

Table 1: Examples from the dataset annotated with variants of speaker and domain tags.

full-dialogue classifier for our submission.

Context-level MT Finally, we explore using linguistic context (varying numbers of previous utterances) to improve translation, with the aim that previous context can provide vital information for disambiguation or adaptation. We use the approach of concatenating varying numbers of previous sentences to the current sentence, separated by a sentence boundary token `<break>` (Tiedemann and Scherrer, 2017; Bawden et al., 2018). This simple strategy was shown to be one of the most effective in a recent comparison of document-level MT approaches (Lopes et al., 2020). To distinguish between different speakers, we also add the speaker tag to the beginning of every utterance. The models are trained to translate both the context and the utterance into the target language (i.e. n-to-n strategy). The candidate utterance is then extracted from the generated output in a preprocessing step. Since the dialogues are bilingual (the agent and customer are speaking in different languages), the original versions of the previous sentences can be either in English or in German. While we always translate both the context and the current sentence into the target language on the target side, we consider two approaches to incorporate context in the source sentence: (i) `ORIG`: each previous sentence is in the original language of its speaker (if the context and current sentences are not produced by the same speaker, our input will be a mix of English and German) and (ii) `SAME`: the source context is provided in the same language as the current sentence (language consistency in the source input). At test time, this requires translating utterances sentence by sentence (as opposed to batch decoding); when the previous utterances are not from the same speaker, they must first be translated by the MT model in the opposite language direction for them to be used as context for the current sentence.

4 Experimental setup

We compare two neural MT base system types, both WMT'19 news translation task submissions: UEDIN (University of Edinburgh; Bawden et al. 2019a and FAIR (Facebook; Ng et al. 2019). All models are transformer-big models (Vaswani et al., 2017): 6 encoder and 6 decoder layers, model dimension of 1024, 16 heads except that UEDIN has a feedforward dimension of 4096 for both the encoder and decoder, and FAIR models increase this dimension to 8192 in the encoder. UEDIN models are implemented in Marian (Junczys-Dowmunt et al., 2018) and FAIR models in Fairseq (Ott et al., 2019). Both model types are trained on parallel and backtranslated monolingual data from the WMT'19 news translation shared task (Barrault et al., 2019). For our final submission (using the base FAIR model), we also use noisy channel reranking (Yee et al., 2019), which requires MT models in both directions and a (target) language model. We describe the data processing techniques in Appendix A and list the hyper-parameters in Appendix B.

5 Experimental Results and Analysis

We report automatic evaluation results in Section 5.1 and provide a qualitative manual comparison in Section 5.2.

5.1 Automatic evaluation results

We report BLEU scores (Papineni et al., 2002), calculated with SACREBLEU[8] (Post, 2018) on the dev set (beam size of 4).

Pretraining The results in Table 2 show that in-domain fine-tuning of the pretrained models always gives large gains. The pre-trained FAIR models are better than the pre-trained UEDIN models (Barrault et al., 2019). Fine-tuning on filtered paracrawl and then on the in-domain data gives a slight gain for the UEDIN models (particularly for de–en) but slightly degrades the FAIR models. We choose to take as a base the models fine-tuned on filtered paracrawl to fine-tune all subsequent models (with tags and context). Though these models perform similar to the FT_1 models, as these were trained on more data, they are likely to be more robust on unseen data. Note that all pretrained models

[8]Default parameters and case-sensitive evaluation.

outperform the baseline models trained just on the chat training data (shown in the first row).

Model	en–de UEDIN	en–de FAIR	de–en UEDIN	de–en FAIR
Chat baseline	33.2	35.8	37.4	30.9
Pretrained	42.5	41.0	44.9	48.5
+ in-domain (FT_1)	58.6	61.4	61.0	62.3
+ paracrawl (FT_2)	44.8	45.4	46.5	45.2
+ in-domain	58.8	60.8	60.9	62.2

Table 2: BLEU scores on the dev set for both pretrained models, and of each model fine-tuned on (i) in-domain data and (ii) filtered paracrawl then in-domain data.

Effect of adding tags As shown in Table 3, we observe that in general the performance of both systems improves with the addition of tags. The use of speaker tags improves the BLEU scores for UEDIN models while dialogue tags improve the BLEU scores for FAIR models. We did not observe an improvement in BLEU scores in models using both the tags over models that used a single tag.

Model	en–de UEDIN	en–de FAIR	de–en UEDIN	de–en FAIR
FT_2 + no tag	58.8	60.8	60.9	62.2
FT_2 + speaker	59.4	61.3	60.1	62.1
FT_2 + domain	59.6	**61.5**	60.8	**62.7**
FT_2 + speaker + domain	59.6	61.1	61.4	61.6

Table 3: Dev set BLEU scores for fine-tuning with tags.

Context-level MT As shown in Table 4, the contextual models perform similarly to the baseline for FAIR models while the performance degrades slightly with the UEDIN models. Increasing the number of contextual sentences degrades BLEU scores, most likely due to the necessity to translate longer sentences. It is also likely that the MT systems do not benefit from the addition of previous sentences because the particular chat dataset used contains utterances that do not need context to be correctly translated, contrary to expectations but in line with findings by Mosig et al. (2020). Using context in the same language (SAME) was more beneficial than the original context (ORIG). It is evident that SAME would perform better than ORIG as the pre-trained models were never exposed to such mix-language utterances. Despite fine-tuning a monolingual encoder on mix-language utterances, ORIG systems perform well.

Final submission Table 5 shows the results of our primary submission on both the dev and test

Model	en–de UEDIN	en–de FAIR	de–en UEDIN	de–en FAIR
FT_2 + in-domain	58.8	60.8	60.9	62.2
In-domain data uses previous context (ORIG language)				
FT_2 + 1 prev	58.2	60.3	58.9	**61.8**
FT_2 + 2 prev	56.1	60.2	58.7	61.5
FT_2 + 3 prev	53.3	59.5	56.7	61.7
In-domain data uses previous context (SAME language)				
FT_2 + 1 prev	58.1	61.0	59.2	**62.2**
FT_2 + 2 prev	57.5	60.1	59.1	61.5
FT_2 + 3 prev	55.4	60.5	57.3	62.1

Table 4: Dev set BLEU scores for contextual MT models. The numbers before "prev" are the number of previous utterances used as context.

Model(FAIR)	en–de dev	en–de test	de–en dev	de–en test
FT_2 + domain-tags	61.5	**60.3**	62.7	60.6
+ noisy-channel re-ranking	62.0	60.1	62.9	61.8
+ ensemble [primary]	62.1	60.2	63.1	**62.4**
FT_1 [contrastive]	61.4	60.2	62.3	61.8
FT_2 + 1-same [contrastive]	61.0	59.8	62.2	61.5

Table 5: The method-wise ablation of our final submission: a 4-model ensemble of FAIR based FT_2 models fine-tuned with in-domain training data tagged with domain tags. The outputs are obtained through noisy-channel reranking.

sets: a 4-model ensemble, each model trained by first fine-tuning the pre-existing FAIR model on filtered paracrawl data, then on in-domain training data tagged with dialogue tags and then reranked using noisy channel reranking (n=20) (Yee et al., 2019). We note that noisy channel reranking is more effective for en–de than for de–en. Ensembling provides limited gains. We report our contrastive submissions for comparison. Our models were chosen on their respective performances on the dev set. We observe that the trends for dev set and test set are similar except for FT_2 + domain-tags model without the noisy channel re ranking.

5.2 Qualitative Evaluation

As the gains in BLEU scores with different configurations are limited, it is difficult to identify if the models exhibit qualitative improvement. We created an evaluation set by selecting around 40 peculiar utterances in each translation direction from the development set and conducted an informal human evaluation by assigning scores of -1, 0 or 1 to poor, acceptable or particularly good translations. The average score was used to guide model selection. As per the qualitative evaluation, there

were few and similar errors across different models to draw any significant conclusions. Notably, the number of errors was higher for the en–de direction due to the production of literal translations. Our primary submission achieved a score of 85.357 on human evaluation using direct assessment.

6 Discussion and Future Work

We observe that fine-tuning the WMT'19 news-adapted models on in-domain chat data is a strong baseline. The addition of tags, though helpful, has limited gains on BLEU, and the addition of context (intuitively an important component for any dialogue related task) actually degrades results. We speculate that this is due to the nature of the original dataset, which has limited linguistic diversity and utterances that are mostly context-independent (Mosig et al., 2020). The overall translation of this dataset was of excellent quality, allowing easy understanding of the dialogues. However, the translated chats exhibit translationese and in some cases lacked naturalness, also the case of the references themselves. An interesting avenue for data collection would be a spontaneous generation of chats in two different languages which can roughly follow the same discourse as in (Bawden et al., 2019b).

Acknowledgements

We thank Ulrich Germann for providing us with the pretrained UEDIN models and FAIR for making their models publicly available. Christian Hardmeier was supported by the Swedish Research Council under grant 2017-930. Abstract

Machine Translation (MT) is a sub-field of Artificial Intelligence and Natural Language Processing that investigates and studies the ways of automatically translating a text from one language to another. In this paper, we present the details of our submission to the WMT20 Chat Translation Task, which consists of two language directions, English→German and German→English. The major feature of our system is applying a pre-trained BERT embedding with a bidirectional recurrent neural network. Our system ensembles three models, each with different hyperparameters. Despite being trained on a very small corpus, our model produces surprisingly good results.

1 Introduction

The language of chat texts is considered a common language where people are rarely paying attention to correct spelling. Therefore, using the traditional methods of Machine Translation (MT), like dictionaries, is insufficient (Hernández, 2009). As deep learning (DL) models are becoming more evolved and complex, this motivates the natural language processing (NLP) community researchers to employ them for challenging tasks such as MT of informal language, such as what is used in chat. Techniques like contextual word embeddings and pre-trained DL models are becoming very common in natural language generation (NLG) tasks such as MT (Kusner et al., 2015; Zou et al., 2013; Abdullah and Shaikh, 2018; Al-Bdour et al., 2019).

The Chat Translation Task is a new task in the Fifth Conference on Machine Translation (WMT20).[1] Translating chat text, specifically the chats of customer support, is a main and exciting task in the field of MT. This kind of tasks has not been widely considered in previous MT studies, mostly because of the absence of openly existing datasets. The target of this new Chat Translation Task is to translate the customer support chat text from English to German and vice versa. The essential goal of this task is to develop models that can translate conversational text and study the use of multilingual models.

We take part in the WMT20 shared chat translation task in two language directions: English→German and German→English. In this paper, we discuss our submission for this task, which is based on the bidirectional recurrent neural networks (bi-RNN) (Schuster and Paliwal, 1997) and using the pre-trained BERT embedding, known as bert-base-multilingual-cased (Devlin et al., 2018).

This paper is constructed as follows. In Section 2, the task and data descriptions are provided. Section 3 discusses our proposed model. Section 4 shows the experiments we conduct and their results. Finally, the Conclusion is in Section 5.

2 Task and Data Description

The Chat Translation shared task of WMT20 offers participants the opportunity to address a challenging problem faced by many companies today as they expand their customer support units to multiple different languages.

The shared task provides a dataset consisting of a set of conversations between agents and customers. The organizers supplied a corpus for the English-German language pair. Specifically, the task involves translating the chat text of an agent speaking English and a customer speaking German. We are asked to translate the agent's chat text from English to German, and the customer's from German to English.

The dataset used for this shared task depends on the corpus of Taskmaster-1 (Byrne et al., 2019),

[1] http://www.statmt.org/wmt20/chat-task.html

Proceedings of the 5th Conference on Machine Translation (WMT), pages 479–482
Online, November 19–20, 2020.

which has the English language, and it consists of dialogues in six fields. A small part of this dataset was chosen and translated to German. The shared task has been provided with train, development, and test sets in JSON format. Each chat in the data file has a specific structure. Table 1 shows the number of conversations in each file of the dataset.

Dataset	# of Conversation
Train dataset	550
Dev dataset	78
Test dataset	78

Table 1: Number of conversations in each set.

Each conversation contains a speaker (who is either an agent or a customer), a source chat text, and a target chat text. For the test set file, we are asked to translate the source chat text to target depending on the speaker. If it is an agent, the translation is from English to German. Otherwise, the translation is from German to English. For evaluating the participating models, the task organizers employ both automatic metrics (BLEU (Papineni et al., 2002) and TER (Snover et al., 2006)) as well as human evaluation.

3 JUST System

Our System follows the sequence of steps shown in Figure 1. In the following subsections, we discuss each step in details.

3.1 Preprocessing Data

For the dataset preprocessing, we first converted the files from JSON file, as given in the shared task, to text files, so we can work with them easily. The training, dev, and test sets are divided into two groups: one that contains the agent as the speaker (English→German) and one that contains the customer as the speaker (German→English). Table 2 shows the number of examples in each group.

Groups	Train	Dev	Test
Agent	7,629	1,040	1,133
Customer	6,215	862	967

Table 2: Number of examples in each group.

3.2 Extracting Features

After preparing the dataset and preprocessing it, we use the pre-trained BERT model to get the word embeddings of the dataset. Specifically, we use Bert-base-multilingual-cased[2] to extract feature vectors of the dataset to be used in the training of our models. For each word in the sentence of the encoder side, we get a file containing the word's embedding. The same is done for the decoder side.

3.3 The System Architecture

Our system is an adaptation of OpenNMT[3], an open-source toolkit for neural machine translation (NMT) (Klein et al., 2017). It is created on the PyTorch framework (Paszke et al., 2017). After ensuring that the dataset is ready to be trained in our system, we feed our dataset to the bi-RNN with long short-term memory (LSTM) cells (Hochreiter and Schmidhuber, 1997) and an attention mechanism (Luong et al., 2015) along with the word embeddings we extract from the dataset and trained everything jointly. For each different set of hyperparameters, we train the model separately. We save the best three models. Table 3 shows the different hyperparameters used for the three models as well some of the experiments that have been done using GloVe embedding (Pennington et al., 2014) + byte pair encoding (BPE) (Sennrich et al., 2015) with a vocabulary of 10K sub-word units (Experiment-1), GloVe + without BPE (Experiment-2), and the default model. The rest of the hyperparameters are left at their default value.

Models	Batch size	Dropout	BPE	Embedding
Default	64	0.3	Yes	GloVe
Experiment-1	64	0.4	Yes	GloVe
Experiment-2	64	0.3	No	GloVe
Model-A	32	0.6	No	BERT
Model-B	100	0.7	No	BERT
Model-C	182	0.7	No	BERT

Table 3: Different hyper parameters of the three models.

We also experiment with the celebrated Transformer mode (Vaswani et al., 2017). However, this model results in very low BLEU scores when evaluated on the dev set. Moreover, it takes about four days to finish training in one experiment. So, we decide to exclude it from further consideration.

3.4 Model Ensembling

Before the test set is released, we train different models using the training set and evaluate them

[2]https://github.com/google-research/bert
[3]https://opennmt.net/OpenNMT-py/options/train.html

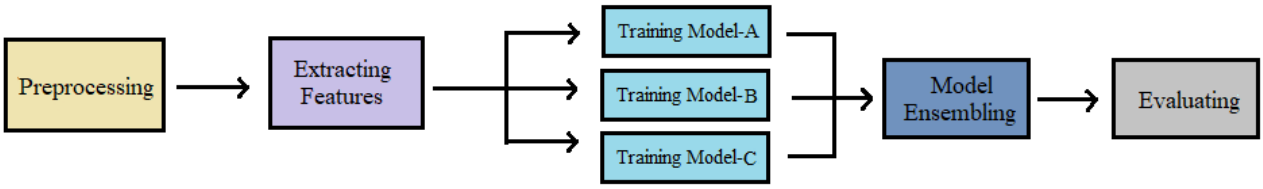

Figure 1: Flowchart of our system.

using the dev set. After training our system, we choose the best three models and ensemble them to get the final output.

4 Results

The results based on the dev set are show in Table 4. The table shows the results of our three models, which we choose for the ensembling step, as well as the other experiments mentioned earlier. The Table shows the difference between them using the BLEU score. From the above table we can notice that training without using BPE improves the results. Moreover, we have chosen the pre-trained BERT because it improves the results compared to the GloVe embedding.

Models	BLEU
Default	32.99
Experiment-1	34.80
Experiment-2	35.21
Model-A	36.88
Model-B	37.07
Model-C	40.93

Table 4: Results of our experiments for the dev dataset.

For evaluation on the test set, we combine the train and dev dataset of each group into one file. Table 5 shows the number of examples in each group after combining them into one file.

	Agent	Customer
Combined train + dev	8,669	7,077

Table 5: Number of examples after combining the files.

We train each group separately and then we ensemble the three models into one. This model is used to get the target of each sentence in the test set of each group. It is worth mentioning that we only use the small dataset provided with the shared task.

Table 6 shows the results for the human evaluation between the human, best score and our model for the English→German scores.

Team	Agent Ave.
Human	91.43
Best	88.21
Our Model	63.93

Table 6: Results of the human evaluation.

Table 7 shows the results we get in the shared task compared to the baseline and the best results. We can see that the agent BLEU score of our model is higher than the baseline, which is translating from English to German. On the other hand, the customer BLEU score for the baseline beat our model, which is translating from German to English.

5 Conclusion

This work describes JUST's submission to the WMT20 chat translation task. For all two translation directions, English→German and German→English, we used the pre-trained BERT embedding with the bi-RNN. We trained one model with different hyperparameters and then ensembled to one final system to translate the test set provided by the shared task. At the end of this work, we find out that a simple NMT model with BERT embedding can achieve surprisingly good results even if it is trained on a very small corpus.

Abstract

This paper describes the Tencent AI Lab's submission of the WMT 2020 shared task on chat translation in English⇔German. Our neural machine translation (NMT) systems are built on sentence-level, document-level, non-autoregressive (NAT) and pretrained models. We integrate a number of advanced techniques into our systems, including data selection, back/forward translation, larger batch learning, model ensemble, finetuning as well as system combination. Specifically, we proposed a hybrid data selection method to select high-quality and in-domain sentences from out-of-domain data. To better capture the source contexts, we exploit to augment NAT models with evolved cross-attention. Furthermore, we explore to transfer general knowledge from four different pre-training language models to the downstream translation task. In general, we present extensive experimental results for this new translation task. Among all the participants, our German⇒English primary system is ranked the second in terms of BLEU scores.

1 Introduction

Although neural machine translation (NMT, Bahdanau et al., 2015; Vaswani et al., 2017; Gehring et al., 2017) has achieved great progress in recent years, translating conversational text is still a challenging task due to its inherent characteristics such as discourse awareness (Maruf et al., 2018; Wang et al., 2019), informality (Wang et al., 2018; Yang et al., 2019) and personality (Mirkin et al., 2015; Wang et al., 2016). This is a task-oriented chat translation task (Wang et al., 2017a; Farajian et al., 2020), which aims to translating conversations between customers and agents. As a customer and an agent can respectively natively speak in German and English, the systems should translate the customer's utterances in German⇒English (De⇒En) while the agent's in German⇐English (De⇐En).

In this paper, we present our submission to the novel task in De⇔En. We explore a breadth of established techniques for building Chat NMT systems. Specifically, our systems are based on the self-attention networks including both sentence- and document-level Transformer (Vaswani et al., 2017; Wang et al., 2017b). Besides, we investigated non-autoregressive translation (NAT) models augmented with our recently proposed evolved cross-attention (Ding et al., 2020). Technically, we used the most recent effective strategies including back/forward translation, data selection, domain adaptation, batch learning, finetuning, model ensemble and system combination. Particularly, we proposed a multi-feature data selection on large general-domain data. We not only use three language models (i.e. n-gram, Transformer and BERT based LMs) to filter low-quality sentences, but also employ feature decay algorithms (FDA, Biçici and Yuret, 2011) to select domain-relevant data. In addition, we explore large batching (Ott et al., 2018) for this task and found that it can significantly outperform models with regular batching settings. To alleviate the low-resource problem, we employ large scale pre-training language models including monolingual BERT (Devlin et al., 2019a), bilingual XLM (Conneau and Lample, 2019) and multilingual mBART (Liu et al., 2020), of which knowledge can be transferred to chat translation models.[1] For better finetuning, we investigate homogenous and heterogeneous strategies (e.g. from sentence-level to document-level architectures). Simultaneously, we conduct fully-adapted data processing, model ensemble, back/forward translation and system combination.

[*] This work was conducted when Li Ding and Liang Ding were interning at Tencent AI Lab. Li Ding is now working at OPPO Research Institute.

[1] We experimented mBART after the official submission.

Proceedings of the 5th Conference on Machine Translation (WMT), pages 483–491
Online, November 19–20, 2020.

According to the official evaluation results, our systems in De⇒En and De⇐En are respectively ranked 2nd and 4th.[2] Furthermore, a number of advanced technologies reported in this paper are also adapted to our systems for biomedical translation (Wang et al., 2020) and news translation (Wu et al., 2020) tasks, which respectively achieve up to 1st and 2nd ranks in terms of BLEU scores. Though our empirical experiments, we gain some interesting findings on the chat translation task:

1. The presented data selection method improves the baseline model by up to +18.5 BLEU points. It helps a lot for small-scale data.
2. The large batch learning works well, which makes sentence-level NMT models perform the best among different NMT models.
3. Our proposed method can improve the NAT model by +0.6 BLEU point, which is still hard to beat its autoregressive teachers.
4. Document-level contexts are not useful on the chat translation task due to the limitation of contextual data.
5. It is difficult to transfer general knowledge from pretrained LMs to the downstream translation task.

The rest of this paper is organized as follows. Section 2 introduces data statistics and our processing methods. In Section 3, we present our system with four different models: sentence-level NMT, document-level NMT, non-autoregressive NMT and NMT with pre-training LMs. Section 4 describes advanced technique integrated into our systems such as data selection and system combination. In Section 5, we reports ablation study and experimental results, which is followed by our conclusion in Section 6.

2 Data and Processing

2.1 Data

The parallel data we use to train NMT systems consist of two parts: in-domain and out-of-domain corpora. The monolingual data used for back/forward translation are all out-of-domain. Table 1 shows the statistics of data in En-De.

[2]The primary systems are ranked according to BLEU. And the official results are listed in http://www.statmt.org/wmt20/chat-task_results_DA.html.

Data	# Sents	# Ave. Len.
Parallel		
In-domain	13,845	10.3/10.1
Valid	1,902	10.3/10.2
Test	2,100	10.1/10.0
Out-of-domain	46,074,573	23.4/22.4
+filter	33,293,382	24.3/23.6
+select	1,000,000	21.4/20.9
Monolingual		
Out-of-domain De	58,044,806	28.0
+filter	56,508,715	27.1
+select	1,000,000	24.2
Out-of-domain En	34,209,709	17.2
+filter	32,823,301	16.6
+select	1,000,000	14.5

Table 1: Data statistics after pre-processing. Note that in-domain/valid/test set is speaker-ignored combined and their average lengths are counted based on En/De.

In-domain Parallel Data The small-scale in-domain corpus is constructed by the task organizer.[3] The training, validation and test sets contain utterances in task-based dialogues with contextual information. We use both w/ and w/o context formats for training corresponding models. Although there exists duplicated/noisy sentences, we do not further filter such limited data.

Out-of-domain Parallel Data The participants are allowed to use all the training data in the News shared task.[4] Thus, we combine six corpora including Europarl, ParaCrawl, CommonCrawl, TildeRapid, NewsCommentary and WikiMatrix. We first filter noisy sentence pairs (as detailed in Section 2.2) and simultaneously select parts of them as pseudo-in-domain data (as detailed in Section 4.1).

Out-of-domain Monolingual Data Due to the high degree of sentence similarity within the TaskMaster monolingual corpus,[5] participants are not allowed to use the in-domain monolingual data to train their systems. Thus, we collect part of monolingual data in news domain, which consists of CommonCrawl and NewsCommentary. We conduct data selection (in Section 4.1) to select similar amount of sentences for back/forward translation.

[3]https://github.com/Unbabel/BConTrasT.

[4]http://www.statmt.org/wmt20/translation-task.html.

[5]https://github.com/google-research-datasets/Taskmaster.

We do not use larger monolingual corpora (e.g. CommonCrawl) and leave this for future work.

2.2 Processing

Pre-processing To pre-process the raw data, we employ a series of open-source/in-house scripts, including full-/half-width conversion, Unicode conversation, punctuation normalization, tokenization and true-casing. After filtering steps, we generate subwords via Joint BPE (Sennrich et al., 2016b) with 32K merge operations.

Filtering To improve the quality of data, we filter noisy sentence pairs according to their characteristics in terms of language identification, duplication, length, invalid string and edit distance. According to our observations, the filtering method can significantly reduce noise issues including misalignment, translation error, illegal characters, over-translation and under-translation.

Post-processing After decoding, we process detokenizer and de-truecaser on system outputs. We found that the toolkit can not precisely deal with all cases. Thus, we automatically fix these bugs according to bilingual agreement.

3 Models

We adopt four different model architectures namely: SENT, DOC, NAT and PRETRAIN.

3.1 Sentence-level NMT (SENT)

We use standard TRANSFORMER models (Vaswani et al., 2017) with two customized settings. Due to data limitation, we use the small settings (SENT-S)[6] with regular batch size (4096 tokens $\times$ 8 GPUs). Based on the base settings (SENT-B),[7] we also empirically adopt big batch learning (Ott et al., 2018) (16348 tokens $\times$ 4 GPUs) with larger dropout (0.3).

3.2 Document-level NMT (DOC)

To improve discourse properties for chat translation, we re-implement our document-level model (Wang et al., 2017b) on top of TRANSFORMER. Its addition encoder reads $N = 3$ previous source sentences as history context and the representations are integrated into the standard NMT

[6] https://github.com/pytorch/fairseq/blob/master/fairseq/models/transformer.py#L947.

[7] https://github.com/pytorch/fairseq/blob/master/fairseq/models/transformer.py#L902.

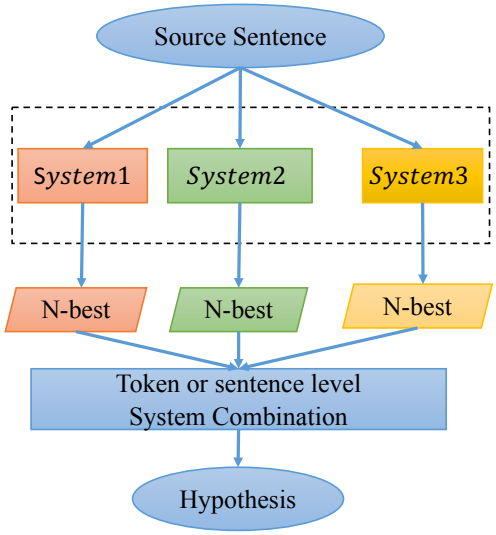

Figure 1: The simplified system combination process, into which we feed each system/model with the source sentence, in turn obtain corresponding n-best result. After pooling all system results, we can perform the token-level or sentence-level system combination decoding and obtain the final hypothesis.

for translating the current sentence. The other configures are same as SENT with small settings.

3.3 Non-autoregressive NMT (NAT)

Different from autoregressive NMT models that generate each target word conditioned on previously generated ones, NAT models break the autoregressive factorization and produce target words in parallel (Gu et al., 2018). Although NAT is proposed to speed up the inference, we exploit it to alleviate sequential error accumulation and improve the diversity in conversational translation. To adequately capture the source contexts, we proposed evolved cross-attention for NAT decoder by modeling the local and global attention simultaneously (Ding et al., 2020). Accordingly, we implement our method based on the advanced MaskPredict model (Ghazvininejad et al., 2019)[8], which uses the conditional mask LM (Devlin et al., 2019a) to iteratively generate the target sequence from the masked input.

3.4 Pretraining NMT (PRETRAIN)

To transfer the general knowledge to chat translation models, we explore to initialize (part of) model parameters with different pretrained language/generation models. Li et al. (2019) showed

that large scale generative pretraining could be used to initialize the the document-level translation model by concatenating the current sentence and its context. We follow their work to build the BERT→DOC model. Furthermore, Conneau and Lample (2019) proposed to directly train a novel cross-lingual pretraining language model (XLM) to facilitate translation task. Accordingly, we adopt XLM pretrained model[9] to sentence-level NMT (XLM→SENT). More recently, Liu et al. (2020) proposed a sequence-to-sequence denoising auto-encoder pre-trained on large-scale monolingual corpora in many languages using the BART objective. As they showed promising results on document translation, we additionally conducted the experiment on Chat data after submitting our systems.[10]

4 Approaches

We integrated advanced techniques into our systems, including data selection, model ensemble, back/forward translation, larger batch learning, finetuning, and system combination.

4.1 Data Selection

Inspired by Ding and Tao (2019), multi-feature language modelling can select high-quality data from a large monolingual or bilingual corpus. We present a four-feature selection criterion, which scoring each sentence by BERT LM (Devlin et al., 2019b), Transformer LM (Bei et al., 2018), N-gram LM (Stolcke, 2002) and FDA (Biçici and Yuret, 2011). Three LMs are complement each other on measuring qualities of sentences while FDA can measure its domain relevance given a in-domain dataset. Sentence pairs in the out-of-domain corpus are ranked by a sum of the above feature scores, and we selected top-M instances as pseudo-in-domain data. According to our observations, the selected data can maintain both high-quality and in-domain properties. For BERT LMs, we exploit two models built by Google[11] and our Tencent AI Lab, which are trained on massive multilingual data. The Transformer LM is trained on all in-domain and out-of-domain data via Marian.[12] Besides, we used FDA toolkit[13] to score domain relevance between in-domain and out-of-domain data.

4.2 Checkpoint Average and Model Ensemble

For each model, we stored the top-L checkpoints according to their BLEU scores (instead of PPL or training time) on validation set and generated a final checkpoint with averaged weights to avoid stochasticity. To combine different models (maybe different architectures), we further ensembled the averaged checkpoints in each model. In our preliminary experiments, we find that this hybrid combination method outperforms solely combining checkpoints or models in terms of robustness and effectiveness.

4.3 Finetuning

We employ various finetuning strategies at different phases of training. For Sent-Out→Sent-In finetune (same architecture but different data), we first train a sentence-level model on large pseudo-in-domain data and then continuously train it on small in-domain data. We apply similar strategy for Doc-Out→Doc-In finetuning, and the only difference is to use document-level data. However, pseudo-in-domain data have no document-level contexts

and we use "$\langle/s\rangle$" symbols as their pseudo contexts (Kim et al., 2019; Li et al., 2020). Besides, we conduct Sent-Out→Doc-In finetuning (different architectures and data). Specifically, we first train a sentence-level model on pseudo-in-domain data and then use parts of corresponding parameters to warm-up a document-level model, which will be continuously trained on in-domain data.

4.4 Back/Forward Translation

Following Section 2, we obtain processed monolingual data. For back translation (BT), we use the best backward translation model to translate from target to source side and produce the synthetic corpus, which is used to enhance the autoregressive NMT models (Sennrich et al., 2016a). About forward translation (FT), we employ forward translation model to perform sequence distillation for NAT models (Kim and Rush, 2016) .

4.5 System Combination

As shown in Figure 1, in order to take full advantages of different systems ($\mathcal{M}odel_1$, $\mathcal{M}odel_2$ and $\mathcal{M}odel_3$), we explore both token- and sentence-level combination strategies.

Token-level We perform token-level combination with confusion network. Concretely, our method follows Consensus Network Minimum Bayes Risk (ConMBR) (Sim et al., 2007), which can be modeled as $E_{ConMBR} = \text{argmin}_{E'}\mathcal{L}(E', E_{con})$, where E_{con} was obtained as backbone through performing consensus network decoding.

Sentence-level We employ the reranking strategy to combine sentence-level systems. Particularly, the sentence reranker contains the best left-to-right (L2R) translation model, R2L (right-to-left) translation model and T2S (target-to-source) translation model. They are integrated by K-best batch MIRA training (Cherry and Foster, 2012) on valid set.

Systems	Integration	BLEU
Models		
SENT-B	IN	42.56
	IN+OUT	**59.81**
SENT-S	IN	41.87
	IN+OUT	58.62
DOC	IN	45.65
	IN+OUT	51.12
	IN→IN	51.93
NAT	IN+OUT	54.01
	*IN+OUT	54.59
Pretrain		
SENT→DOC	OUT→IN	49.77
	OUT→IN+OUT	51.58
XLM→SENT	IN+OUT	**59.61**
BERT→DOC	IN+OUT	56.01
MBART→SENT	IN+OUT	57.48

Table 4: BLEU scores of SENT, DOC, NAT and PRE-TRAIN with different finetuning strategies on En⇒De.

5 Experimental Results

Unless otherwise specified, reported BLEU scores are calculated based on *combined* and *tokenized* validation set by *muti-bleu.perl*, which is different from the official evaluation method.

5.1 Ablation Study

Table 2 investigates effects of different settings on translation quality. We then apply the best hyper-parameters to the models in Section 4 if applicable.

Effects of Model Average and Ensemble Following Section 4.2, we averaged top-L checkpoints in SENT-B model and found that it performs best when $L = 5$. We followed the same operation for SENT-S model and then combined two best averaged models (one from SENT-B and the other one from SENT-S) via ensemble method. As shown in Table 2(a), the ENS model (i.e. "average + ensemble") performs the best.

Effects of Beam Size and Length Penalty Table 2(b) and 2(c) report BLEU scores of SENT-B model using different beam size and length penalty,

# Methods	En⇒De	De⇒En
SENT-S	**59.12**	**59.61**
+BT	59.05	59.22
SENT-B	**60.33**	**59.53**
+BT	59.34	58.94
+FT	59.80	58.94
NAT	54.01	56.58
+FT	**56.56**	**56.69**
XLM	**59.61**	**60.96**
+BT	59.43	58.84

Table 5: BLEU scores of back-translation and forward-translation strategies for different models.

Models	En⇒De		De⇒En	
	-Dom.	+Dom.	-Dom.	+Dom.
Valid Set (combined)				
SENT-S	**60.47**	60.31	**62.66**	61.19
SENT-B	**62.28**	62.08	**64.99**	63.00
XLM	**61.12**	60.85	64.19	**61.30**
Valid Set (split)				
SENT-S	**60.69**	60.48	60.05	**62.09**
SENT-B	61.65	**61.93**	59.64	**63.31**
XLM	**60.90**	60.74	61.12	**62.04**
AVE.	**61.08**	61.05	62.27	**62.48**

Table 6: BLEU scores of domain adaptation strategy for different models.

respectively. As seen, it obtains the best performance when using larger beam size (e.g. 8 or 16). The length penalty prefers around 1.0 because En and De belong to similar language family.

5.2 Main Results

This section mainly reports translation qualities across different models and approaches (in Section 3 and 4). Finally we combine all of them via techniques integration and system combination.

Data Selection Table 3 demonstrates the translation performances of SENT-BASE on different FDA variants. "+Bi-FDA" means using bilingual in-domain data as seed to select N sentences from out-of-domain data while "+Bi-FDA-XL" indicates using larger seed (iteratively add selected pseudo-in-domain data to seed). "Mono" means that we only use source-side data for data selection. As seen, selected data from News domain can help to significantly improve translation quality. However, monolingual selection ("+Mono-FDA-XL") performs better than bilingual one ("+Bi-FDA-XL") and obtain the best BLEU score when $N = 800K$.

Models and Pretraining Table 4 illustrates the translation performances of various NMT models (i.e. SENT, DOC, NAT) with different training strategies. As seen, all models are hungry for larger in-domain data due to the data limitation problem (IN+OUT vs. IN). About sentence-level models, the "base + big batch" setting performs better than the "small" one (SENT-B vs. SENT-S). However, it is difficult for document-level models to outperform sentence-level ones (DOC vs. SENT). The interesting finding is that the document-level model trained on pseudo contexts ("IN+OUT") can improve the baseline that is trained on only real context ("IN") by +5.47 BLEU points. We think there are two main reasons: 1) it lacks of large-scale training data with contextual information; 2) it is still unclear how the context help document translation, which is similar to the conclusion in previous work(Kim et al., 2019; Li et al., 2020). About NAT models, our proposed approach can improve the vanilla NAT by +0.6 BLEU point, which are lower than those of autoregressive NMT models.

About pre-training, we first explore SENT→DOC, which train a sentence-level model and then use part of their parameters to warm-up a document-level model. However, it is still lower than sentence-level models. The performance of BERT→DOC is much better than pure document-level models (56.01 vs. 51.93), which confirms our hypothesis that contextual data is limited in this task. Furthermore, the XLM→SENT can obtain 59.61 BLEU points which are closed to that of SENT-B. The MBART→SENT with CC25 pretrained model can achieve 57.48 BLEU points. We find that performances of most pretraining models can not beat that of the best sentence-level model. There are two possible reasons: 1) needing a number of tricks on finetuning; 2) it is not easy to transfer general knowledge to downstream specific tasks.

Back/Forward Translation Table 5 empirically shows the translation performances of BT and FT for different models, including SENT-S, SENT-B, NAT and PRE-TRAIN. In particular, we performed BT for all systems except NAT, while deploying FT on NAT and SENT-B. As seen, augmenting with monolingual data via BT/FT can not achieve better performances than pure models. The reason

Combination type	En⇒De	De⇒En
Token-level	58.91	59.53
Sentence-level	60.41	62.41

Table 7: Model performance after system combination.

may be that we only use a small part of large-scale monolingual data in news domain. In future work, we will exploit to select in-domain data from the larger monolingual corpus.

Sub-domain Adaptation Modeling of all the speakers and language directions involved in the conversation, where each can be regarded as a different sub-domain. We conduct domain adaptation for different models to avoid performance corruption caused by domain shifting in Table 6. Specifically, we finetune the well-trained models w/ and w/o domain adaptation, denoted as "-Dom." and "+Dom.", and evaluated them on domain *combined* and *split* valid sets. As seen, domain adaptation helps De⇒En more on valid set ("AVE." 61.27 vs. 61.48), while has no much benefits on En⇒De tasks. While evaluating on combined valid sets has a bias towards models without domain adaptation. We attribute this interesting phenomenon to personality and will explore it in the future.

System Combination In order to make full use of the optimal models obtained by the above strategies, we perform token- and sentence-level system combination simultaneously. For each strategy, we generate the n-best candidates to perform the combination. As shown in Table 7, although token-level combination preserves more lexical diversity and avoids the stochasticity, its translation performance is significantly weaker (averagely -2.19 BLEU points) than sentence-level combination. Encouragingly, the sentence-level combination outperforms token-level one on valid set, which is thus used in our final system (in Table 8).

5.3 Official Results

The official automatic evaluation results of our submissions for WMT 2020 are presented in Table 8. For the primary submission, the SYS-1 combines SENT (ensembled SENT-B and SENT-S), DOC and NAT models. As contrastive submissions, the SYS-2 combines SENT and XLM models while the SYS-3 combines SENT, DOC, NAT and XLM ones. Among participated teams, our primary systems achieve the second and the forth BLEU scores on De⇒En and En⇒De, respectively.

Systems	En⇒De		De⇒En	
	Valid	Test	Valid	Test
SYS-1	60.41	58.6	62.41	62.3
SYS-2	58.91	53.6	59.53	54.0
SYS-3	60.42	58.6	62.40	61.9
BEST	–	60.4	–	62.4

Table 8: Official BLEU scores of our submissions for WMT20 Chat task. The BEST denotes the best BLEU scores of systems submitted by participants.

6 Conclusion

The paper is a system description for the Tencent AI Lab's entry into the WMT2020 Chat Translation Task. We explore a breadth of established techniques for building chat translation systems. The paper includes numerous models making use of sentence-level, document-level, non-autoregressive NMT. It also investigates a number of advanced techniques including data selection, model ensemble, finetuing, back/forward translation and initialization using a pretrained LMs. We present extensive experimental results and hope that this work could help both MT researchers and industries to boost the performance of discourse-aware MT systems (Hardmeier, 2014; Wang, 2019).

Acknowledgments

The authors wish to thank the organizers of WMT2020 Chat Translation for their prompt responses on our questions. The authors also specially thank Dr. Xuebo Liu (University of Macau) and Dr. Siyou Liu (Macao Polytechnic Institute), who kindly support us by their engineering and linguistic suggestions, respectively.

Combining Sequence Distillation and Transfer Learning for Efficient Low-Resource Neural Machine Translation Models

Raj Dabre **Atsushi Fujita**
National Institute of Information and Communications Technology
3-5 Hikaridai, Seika-cho, Soraku-gun, Kyoto, 619-0289, Japan
firstname.lastname@nict.go.jp

Abstract

In neural machine translation (NMT), sequence distillation (SD) through creation of distilled corpora leads to efficient (compact and fast) models. However, its effectiveness in extremely low-resource (ELR) settings has not been well-studied. On the other hand, transfer learning (TL) by leveraging larger helping corpora greatly improves translation quality in general. This paper investigates a combination of SD and TL for training efficient NMT models for ELR settings, where we utilize TL with helping corpora twice: once for distilling the ELR corpora and then during compact model training. We experimented with two ELR settings: Vietnamese–English and Hindi–English from the Asian Language Treebank dataset with 18k training sentence pairs. Using the compact models with 40% smaller parameters trained on the distilled ELR corpora, greedy search achieved 3.6 BLEU points improvement in average while reducing 40% of decoding time. We also confirmed that using both the distilled ELR and helping corpora in the second round of TL further improves translation quality. Our work highlights the importance of stage-wise application of SD and TL for efficient NMT modeling for ELR settings.

1 Introduction

Neural machine translation (NMT) (Bahdanau et al., 2015; Sutskever et al., 2014) enables end-to-end training of translation models and is known to give state-of-the-art results for a large variety of language pairs. NMT models with large hidden sizes or deep stacked layers tend to give better translations than those with small hidden sizes or fewer layers. Large models inevitably need more storage space and computation, and are difficult to deploy on low-computation and low-memory devices. Additionally, beam search decoding is known to improve translation quality but needs more computation and is unacceptable in a low-latency real-time application where faster decoding is as valuable as if not more valuable than translation quality. Consequently, neural models that are compact and fast are extremely important and a growing body of research known as neural model efficiency focuses on this issue.

One of the most popular techniques to train efficient models is knowledge distillation (Hinton et al., 2015) which relies on transferring the knowledge learned by a large model (called teacher) into a smaller model (called student). Sequence distillation (SD) (Kim and Rush, 2016) is a special case of knowledge distillation for sequence-to-sequence models, such as those used for NMT. Not only does it help in the training of compact and fast models with high translation quality, it sometimes helps in eliminating the need for beam search which further increases decoding speed. SD relies on the creation of distilled parallel corpora by translating the training source sentences into the target language by using a large model. The distilled corpora are simplified representations of how the large model sees the original corpora and their quality will have a direct impact on the translation quality of compact models trained with them.

While SD is known to perform extremely well for high-resource settings, its direct application to extremely low-resource (ELR) settings will not work due to over-fitting. Table 1 gives the BLEU scores (Papineni et al., 2002) for Vietnamese–English (Vi–En) and Hindi–English (Hi–En) translation tasks in the Asian Languages Treebank (ALT) (Riza et al., 2016),[1] where Transformer Base models (Vaswani et al., 2017) with 1, 2, 3, and 6 encoder and decoder layers were trained on the ALT training data of 18k sentence pairs. It is clear that there is a huge performance gap between the

Table 1: The impact of number of encoder-decoder layers on translation quality: BLEU scores of greedy (G) and beam search (B, beam size of 4).

6-layer models and shallower ones. Thus, distilled corpora generated using shallower models will certainly hurt the translation quality of compact models. However, when we used the 6-layer models to generate distilled corpora, the translations were almost identical to the reference translations (with almost 100 BLEU). The reason is over-fitting despite the use of classic regularization methods such as dropout. Consequently, we need to rely on helping corpora through transfer learning (TL) methods. TL can be used by itself to improve the performance in ELR settings regardless of model efficiency. However, very little is known about how SD and TL work together.

In this paper, we investigate how to train efficient (compact and fast) NMT models for ELR settings with helping corpora through domain adaptation or cross-lingual TL. We use TL twice: once for distilling ELR corpora and then for training efficient models. We expect that training multi-domain or cross-lingual models by simply concatenating, without oversampling, the ELR corpora with the helping corpora leads to NMT models that can help generate useful distilled corpora.

To evaluate the effect of our proposed method, we experimented with two ELR language pairs, Vietnamese–English and Hindi–English (4 translation directions), in the ALT dataset. When we trained compact NMT models with 40% fewer parameters only on the distilled ELR corpus, the resulting models showed improved translation quality with greedy search by 3.6 BLEU points in average over the models trained on the original ELR corpus, while reducing 40% of decoding time. Furthermore, when we jointly used the distilled ELR corpora with the helping corpora via TL, the quality of the resulting compact models was further improved by up to 3.7 BLEU points over the best score achieved by using no distilled data. This highlights the importance of stage-wise application of SD and TL for efficient NMT models in ELR settings with high translation quality. Although the individual techniques utilized in this work are not novel, their combination and our empirical observations pertaining to the development of efficient models for ELR settings are novel.

The contributions of our paper are as follows:

- An empirical study of the combination of TL methods and SD for efficient NMT modeling.
- A cost-benefit analysis of efficient models for ELR settings.

2 Related Work

Our work is at the intersection of knowledge distillation (Hinton et al., 2015) and transfer learning for training compact NMT models.

2.1 Sequence Distillation

Knowledge distillation for sequence-to-sequence models have been successful in training efficient (compact and fast) NMT models. Sequence distillation (SD) (Kim and Rush, 2016) for NMT is a simple approach which involves training a large NMT model on a parallel corpus, translating the source side of the corpus, and then using the pseudo-parallel corpus of the same source side and the generated pseudo-target, called distilled corpus, to train a compact NMT model. The pseudo-targets represent the large model's interpretation of the original targets and can be considered as smoothed label sequences. The sequences are simpler and hence easier for smaller models to learn. As our focus is on a simple and efficient solution for ELR settings, we decided to focus only on SD.

However, its impact on ELR settings is uncertain. Given that only few thousands of domain-specific sentences are available, training large NMT models tends to over-fit on the small corpora while compact NMT models will only lead to pseudo-targets of poor quality, both preventing the generation of useful distilled corpora. It is certainly possible to search for an optimal model size. However, it will involve a time-consuming hyper-parameter search, while the result may be specific to given corpora.

2.2 Transfer Learning

Transfer learning (TL) can be in the form of domain adaptation (Chu et al., 2017) or cross-lingual or multilingual transfer (Firat et al., 2016; Zoph et al., 2016; Dabre et al., 2019; Johnson et al., 2017; Dabre et al., 2020) using helping bilingual corpora.

Assume that L_1–L_2 is an ELR language pair and L_3–L_4 is a helping pair. The given parallel corpora

for the two pairs may belong to different domains. Typically, pre-training a model on the larger L_3–L_4 corpus and then **fine-tuning** (**"ft"**) it on the smaller L_1–L_2 corpus is known to give the best translation quality for the L_1–L_2 pair (Zoph et al., 2016; Chu et al., 2017; Dabre et al., 2019), regardless of the number of model parameters. However, without careful regularization, this will definitely lead to the L_1–L_2 corpus being memorized. To address this, joint training of an NMT model using the following two methods on both corpora has been studied:

Mixed Training ("mxt"): Directly train on the concatenated corpus.

Mixed Fine-Tuning ("mxft"): First train on the L_3–L_4 corpus as in "ft," but perform fine-tuning on the concatenated corpus.

Prior to concatenating two corpora, the L_1–L_2 corpus is typically oversampled so that its size matches to the L_3–L_4 corpus. Also, we can prepend the source sentences with two artificial tokens, one indicating the domain of the corpus (Chu et al., 2017), and another indicating the target language into which we want to translate (Johnson et al., 2017). Note that when L_2 and L_4 are the same, the target language tokens are unnecessary. If L_1 and L_3 are also the same, then we are essentially performing domain adaptation.

2.3 Other Related Work

Some recent work tackled efficient NMT modeling in low-resource settings (Goyal et al., 2020; Gordon and Duh, 2020). Whereas they focus on applications of TL for compact models as this paper, there are some key differences between them and ours. Gordon and Duh (2020) focus on low-resource settings, but our low-resource data are significantly smaller than theirs. Second, whereas they use distillation twice and TL once, we recommend distillation once and TL twice. Finally, they do not examine cross-lingual TL for model compression. Goyal et al. (2020) focus on cross-lingual learning, but their approaches are centered more on leveraging orthographic or linguistic similarity, whereas we make no efforts towards orthographic unification. We thus consider parts of these studies to be orthogonal to ours.

Apart from domain adaptation and cross-lingual TL methods, low-resource settings can benefit from monolingual data, for instance, through back-translation (Sennrich et al., 2016), where target language monolingual data are translated into pseudo-source sentences. Recently, pre-training on monolingual data (Devlin et al., 2019; Song et al., 2019; Mao et al., 2020) has been proven to significantly improve the translation quality of ELR settings. Approaches involving helping monolingual data are usually more time-consuming than those that use helping bilingual corpora. Furthermore, given that our approach already needs a reasonable amount of time due to the application of TL and forward-translation of the source sentences of the parallel corpora for distilling them, we consider that such approaches should be used when no more gains can be obtained from helping bilingual corpora. We refer interested readers to work on distillation using unsupervised methods (Sun et al., 2020).

Independent of the application of TL, there exist methods for speeding up NMT, such as weight pruning (See et al., 2016) where model weights close to zero are pruned out, quantization (Lin et al., 2016) where weights are represented by faster to process integers instead of floating point numbers, aggressive model binarization (Courbariaux et al., 2017), and binary code prediction softmax (Oda et al., 2017) where the softmax is sped up by making it predict a binary code representing words instead of one-hot vectors. We expect these methods to further speed up the models obtained using our proposed method.

3 Our Approach: Transfer-Generate-Transfer

Refer to Figures 1 and 2 for a visual overview of our approaches. Figure 1 depicts the application of TL to generate distilled corpora for the ELR settings. Figure 2 depicts how the distilled ELR corpora can be used with the distilled or non-distilled helping corpora to train compact models. Our method for training compact NMT models for ELR settings can be summarized as follows:

1. Train a large joint NMT model using "**mxt**" or "**mxft**" on the concatenation of L_1–L_2 and L_3–L_4 corpora without oversampling L_1–L_2.
2. Use the joint NMT model to decode L_1 into pseudo-L_2 (L_2') and to decode L_3 into pseudo-L_4 (L_4').[2]

[2]Instead, a unidirectional $L_3 \rightarrow L_4$ model can be used to distill the L_3–L_4 corpus, because NMT models trained on the larger corpus will prevent from over-fitting and thereby generate reliable distilled data for this pair.

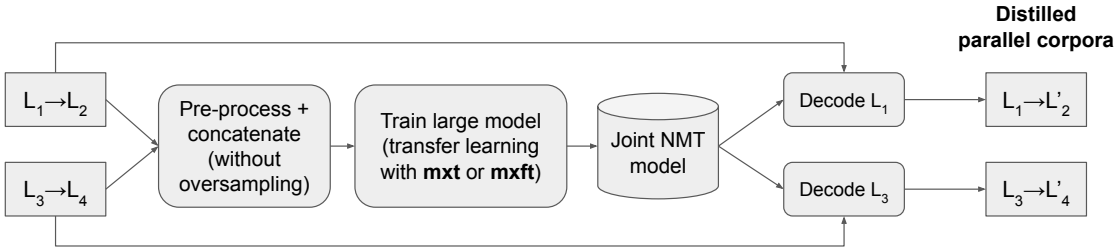

Figure 1: First round of transfer learning: training a joint model to distill the parallel corpus for extremely low-resource language pair (L_1–L_2) by leveraging a helping parallel corpus (L_3–L_4).

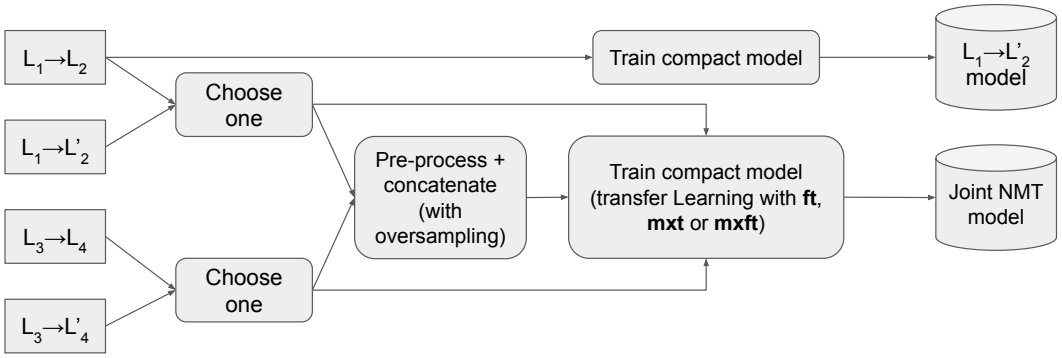

Figure 2: Second round of transfer learning: training an efficient NMT model for extremely low-resource language pairs (L_1–L_2) by leveraging a helping parallel corpus (L_3–L_4), using data distilled via the method in Figure 1. There are four possible ways of combining low-resource and helping corpora as each of them can be either distilled or non-distilled.

3. Train compact NMT models only on the L_1–L_2' corpus, or together with the distilled or non-distilled helping corpora using "**ft**," "**mxt**," or "**mxft**."

Standard TL takes place when both the ELR and helping corpora are non-distilled. In this case, TL is not used to distill data, and the ELR corpus should be oversampled to match the size of the helping corpus to ensure the best translation quality. However, for the purposes of distillation, unlike previous work, we do not oversample the L_1–L_2 corpus before concatenating it with the L_3–L_4 corpus. We did so because our preliminary explorations revealed that oversampling causes the model to memorize the L_1–L_2 corpus, thereby preventing the generation of useful distilled corpora. Naturally, the lack of oversampling might negatively impact on the quality of distilled L_1–L_2' corpus. One can empirically determine an optimal oversampling rate, but we decided to not search for it in order to make our method simple. We address this point in Section 5.1.3 with empirical evidence justifying our choice.

Note that one can pre-train compact NMT models on helping corpora and then fine-tune them on ELR corpora, avoiding SD altogether. However, the quality of TL is proportional to the quality of the pre-trained model, which tends to be high when using larger models. Furthermore, distilled data is prone to be simpler than the original data and thus has higher potential for leading to compact models. We hypothesize that distilling ELR corpora might help in better model compression. We test this hypothesis through experiments.

4 Experimental Settings

To determine the feasibility of the proposed method, we trained and evaluated NMT models in the following two groups of settings.

#1. With only distilled ELR corpora: To determine the impact of different TL settings on the quality of distilled ELR corpora and hence the compact models trained.

#2. With ELR and helping corpora: To determine the settings using both ELR and helping corpora that give compact models with highest possible translation quality.

4.1 Datasets

We experimented with the ELR Vietnamese–English (Vi–En) and Hindi–English (Hi–E) pairs from the Asian Languages Treebank (ALT) with 18,088 training, 1,000 development, and 1,018 test sentence pairs. As for the helping corpora, we used the training part of the IWSLT 2015 Vietnamese–English[3] and the IITB Hindi–English (Kunchukuttan et al., 2018),[4] consisting of 133k and 1.5M lines, respectively. We chose large as well as small helping corpora in order to determine the impact of helping corpora sizes on the model training.

4.2 Implementation Details

We used the Transformer model for our experiments (Vaswani et al., 2017) because it gives the state-of-the-art results for NMT. We made necessary changes to the code in the tensor2tensor v1.14 implementation of the Transformer in order to construct joint sub-word vocabularies as well as to handle oversampling. Tensor2tensor has its own default sub-word vocabulary learning method which we use as is by feeding it the surface word vocabulary list obtained from combining the ALT language pair and the helping language pair vocabularies. We used the default hyper-parameter setting[5] corresponding to "*transformer_base_single_gpu*" and separate source and target sub-word vocabularies of size 8,000. We chose small vocabularies as they are known to give better results for ELR settings by eliminating vocabulary sparsity. Small vocabularies also lead to models with smaller and faster softmax layers which is crucial for model compactness and speed.

We trained our models, evaluating them on the development set BLEU score every 1,000 iterations, and terminated training after 500,000 iterations or when the BLEU score did not change by more than 0.1 BLEU points for 10,000 iterations.

After training, we averaged the final 10 checkpoints to yield a single model for decoding. For decoding the test sets for evaluation, we compared greedy search and beam search with a beam size of 4, using a length penalty (alpha) of 0.6. On the other hand, for decoding the source sentences of the training sets for distillation, we only used beam search with the same beam size.

4.3 Models Evaluated

Our primary goal is to reduce the decoding time while achieving better translation quality than baselines. Following Kim and Rush (2016), who have shown that the number of encoder-decoder layers (L) have a significantly larger impact on decoding speed than hidden sizes (H), we mostly focus on compact models that use fewer encoder-decoder layers. Nevertheless, we also examine smaller hidden sizes in some experiments.

We trained simple baseline models from scratch with 1, 2, 3, and 6 layers only on the ALT training data (see Table 1).

4.3.1 Models for Distilling Corpora

To train joint models for each translation direction that is later used for distilling training data, we disjointly used the helping Vi→En, En→Vi, Hi→En, or En→Hi corpora. As we used separate source and target vocabularies and hence embedding layers, settings with a helping corpus for different translation direction can be a reasonable simulation of cross-lingual TL settings.

For joint training, we compared "**mxft**" and "**mxt**." We also considered the impact of using the domain indicator tokens (Chu et al., 2017). Thus, for each ELR and helping corpora combination, there were four types of joint models, and thus four different versions of distilled data.

4.3.2 Compact NMT Models for ELR Settings

We trained two types of models, ones that use only the distilled ELR corpora and ones that use the ELR as well as helping corpora.

#1. With only distilled ELR corpora: For each of the four helping corpora per translation direction that are used to distill data, we trained models with $L \in \{1, 2, 3\}$ and $H = 512$.[6] Additionally, we trained 3-layer models with $H \in \{128, 256\}$ to further study the tradeoff between model size and translation quality.

#2. With ELR and helping corpora: For each combination of translation direction and helping direction, we first determined the best distilled ELR corpus among four variants on

[3] https://github.com/stefan-it/nmt-en-vi

[4] http://www.cfilt.iitb.ac.in/iitb_parallel/

[5] The important hyper-parameters that remained constant throughout our experiments are: dropout of 0.1, ADAM optimizer with an initial learning rate of 0.1, 16,000 warm-up steps followed by decay for the learning rate, 8 attention heads, and a batch-size of 1,024.

[6] Feed-forward layer filter sizes were always 4 times the model's hidden size throughout this paper.

Model	Vi→En (VE)				En→Vi (EV)				Hi→En (HE)				En→Hi (EH)			
	VE	EV	HE	EH	VE	EV	HE	EH	VE	EV	HE	EH	VE	EV	HE	EH

DT	yes	yes	yes	no	yes	yes	yes	no	yes	no	yes	no	yes	no	yes	yes
$L=6$ $H=512$ (see Table 1)	greedy: 19.4 beam: 20.5				greedy: 24.0 beam: 25.2				greedy: 14.2 beam: 15.2				greedy: 15.0 beam: 16.3			

Table 2: BLEU scores for each ELR translation task achieved by our proposed method with greedy search. The second row indicates the translation direction of helping data. The highest scores for each translation direction are highlighted in bold. "TT" and "DT" respectively represent the type of training ("mxt" or "mxft") and whether domain tags were used ("yes" or "no") for the joint training that led to the best distilled corpora. The last row shows the greedy and beam search BLEU scores of the baseline 6-layer models for comparison (see Table 1).

the basis of BLEU score of the $L = 3$ and $H = 512$ model trained only on it (#1), and then combined it with the distilled helping corpus to train models with $L \in \{1, 2, 3\}$ and $H = 512$ using "**ft**," "**mxt**," and "**mxft**." We also trained models with the same configurations for combinations of ELR and helping corpora where only one of the corpora are distilled. As (strong) baselines, we trained models with $L \in \{1, 2, 3, 6\}$ and $H = 512$ trained on non-distilled ELR and helping corpora.

5 Results

We show results using only distilled ELR corpora and then using it with helping corpora.

5.1 Using Only Distilled ELR Corpora

In Table 2, we show how domain adaptation and cross-lingual TL methods affect creation of distilled ELR corpora and hence the greedy search translation quality of efficient models. Greedy search is emphasized due to our focus on fast decoding speed as well as high translation quality.

5.1.1 Translation Quality of Efficient Models

For each translation direction, the best distilled corpora used to train models with 3 layers gives greedy search translation quality ranging from 1.5 to 4.0 BLEU points over the 6-layer non-distilled baseline model's beam search translation quality. Comparing the 1-, 2-, and 3-layer models trained with the best distilled corpora with their non-distilled counterparts in Table 1, we can see that there is an improvement of 2.9 to 5.5 BLEU points. Considering that we used the distilled equivalents of the original training data, this result shows the explicit effect of TL and SD which helps generate data that improves translation quality despite reducing the model size.

Training models on ELR corpora can finish quickly. Thus, our distilled corpora can be used in situations where quick deployment of compact and fast NMT models is important.

5.1.2 Domain Adaptation vs. Cross-Lingual Transfer

Our experiment revealed that cross-lingual training is definitely a viable alternative. For instance, in Vi→En translation, the best BLEU score was achieved when the helping direction was also Vi→En. When the helping direction was Hi→En, these improvements were much smaller. Nevertheless, it is clear that cross-lingual training is useful when domain adaptation is not possible. Work on script mapping to improve the quality of TL (Song et al., 2020; Goyal et al., 2020) indicates that our cross-lingual distillation procedure might give better results if we mapped Hi to Vi or vice-versa. We leave this for future work.

Consider two hypothetical settings for Vi→En translation, where we used the reversed, En→Vi and En→Hi, helping directions to generate distilled corpora for Vi→En translation. When using En→Vi as the helping direction, the BLEU scores of greedy search with 1-, 2-, and 3-layer models improved by 4.3, 4.4, and 5.6 BLEU points, respectively. These improvements are approximately 1.0 BLEU points lower than those obtained in the domain adaptation setting with Vi→En as the helping direction, but it shows that using helping corpora with different languages can be of some use. However, when using En→Hi as the helping direction, the BLEU scores dropped. Note that English

DT	TT	Vi→En	En→Vi	Hi→En	En→Hi
yes	mxft	21.5	**29.2**	15.3	15.4
yes	mxt	**23.2**	28.0	**16.7**	**18.0**
no	mxft	21.9	29.1	14.2	12.9
no	mxt	21.1	28.0	16.2	16.1

Size	Vi→En		En→Vi		Hi→En		En→Hi	
	HE	EH	HE	EH	HE	EH	HE	EH
133k	20.5	19.2	26.4	25.9	15.2	14.6	16.4	17.1
200k	21.3	**20.2**	27.1	28.0	16.3	15.2	16.4	17.1
500k	**21.5**	19.9	27.1	**28.2**	**17.2**	**15.8**	**17.5**	17.5
1500k	18.9	14.1	**22.7**	23.1	16.7	9.6	13.9	**18.0**

Table 4: Impact of helping corpus size on the greedy search translation quality (BLEU) for each translation task achieved with models with $L = 3$ and $H = 512$. The best scores are in bold.

and Vietnamese use the Roman alphabet which might enable cognate sharing even when the ELR and helping directions are opposite. However, this is not fully applicable when En→Hi is the helping direction. Furthermore, the Hindi–English corpus was much larger than the one for Vietnamese–English. Since we do not oversample the ELR corpora for distilling corpora, we expect that the model heavily focuses on the Hindi–English pair which could negatively impact on the quality of the resulting distilled corpora.

While similar observations are applicable to other translation directions, consider Hi→En and En→Hi translation. As before, using Hi→En and En→Hi helping directions respectively using domain adaptation resulted in the best distilled corpora. However, using the reverse En→Hi and Hi→En helping directions, respectively, led to a drop in translation quality. In contrast, using Vi→En and En→Vi helping directions led to distilled corpora that led to compact models giving translations within 1.0 BLEU points of those given by the best distilled corpora. This shows that in a cross-lingual TL setting for distilling ELR corpora, it may be better to have helping corpora that are not much larger than the ELR corpora. We validate this hypothesis in Section 5.1.3.

As for the use of domain indicator tags, 11 out 16 cases indicate that such tags are useful. In Table 3, we show the results of model with $L = 3$ and $H = 512$ trained on distilled data generated with and without domain indicator tags when training using "mxt" and "mxft" (4 combinations). For simplicity, we show results for when the ELR and helping directions are the same. Using domain tags gives better results when the helping corpora are substantially larger than the ELR corpora. But when the helping corpora are relatively smaller (Vietnamese–English), domain tags do not seem to have a large impact. Furthermore, "mxt" tends to be better than "mxft." Overall, simply concatenating the ELR and helping corpora without oversampling or domain indicators and then training joint model in one stage should be sufficient to yield useful distilled corpora. We will experiment with additional language pairs and domains in the future to conclusively determine a one-fits-all setting.

5.1.3 Impact of Helping Corpora Size

We observed that a large helping corpus degrades the translation quality in cross-lingual settings. Instead of determining an optimal oversampling ratio for the ELR corpus, we experimented with downsampling the helping corpus size. We did this to avoid running into the risk of over-fitting due to oversampling. We experimented with the downsampled versions of the Hindi–English corpus: we prepared sub-corpora with 500k, 200k, and 133k sentence pairs, assuring that a larger one subsumes all the smaller ones. For simplicity, we reused the best configurations reported in Table 2.

Table 4 shows the greedy search results. When using the entire Hindi–English helping corpus for Vi→En and En→Vi translation tasks, the BLEU score is substantially lower than the baseline models, indicating the poor quality of the distilled data. Note that we do not oversample the ELR corpora for distillation and thus coupling them with a larger helping corpus is detrimental to the final translation quality, as the NMT model sees more examples in the latter than the former. However, using significantly smaller corpora ensures that the NMT model sees much fewer examples in the helping corpus and thus is able to better learn from the ELR corpus leading to better distilled data. This is evidenced by the improved BLEU scores when using downsampled helping corpora. Naturally, using the Vi→En helping corpus gives the best results for Vi→En translation tasks, but the results using the downsampled Hindi–English helping corpora are within 2.0 BLEU points of the best. Note also that the BLEU score for Hi→En task using a helping corpus with 500k sentence pairs (17.2) surpasses the

Model		Size	Time	BLEU
$L=1$	$H=512$	19.0M	11.7s	18.4
$L=2$	$H=512$	27.0M	17.6s	20.8
$L=3$	$H=512$	34.0M	22.5s	21.8
$L=3$	$H=256$	11.0M	22.0s	18.8
$L=3$	$H=128$	4.0M	21.3s	17.3
$L=6$ (see Table 1)	$H=512$	56.6M	37.6s	18.2

Table 5: Comparison of size, decoding time (with greedy search), and BLEU score for various models evaluated in Table 2. For each column, average value for four translation directions is reported.

score obtained using all the sentence pairs (16.7) by 0.5 BLEU points. For the reverse direction, the score (17.5) is within 0.5 BLEU points of the best score (18.0). It is clear that choosing an appropriate helping corpus size is important for generating useful distilled corpora. This result further reinforces our claim that cross-lingual training is a viable option for generating useful distilled data. Such cross-lingual training also has the potential to distill data that can help train compact models with BLEU score higher than larger models trained on non-distilled data. As for optimal size of helping corpus, the performance gap between using 200k and 500k helping sentence pairs is very small in most settings. This means that distilling data does not need too much helping corpus and thus in practice choosing a small sample of the helping corpus can help significantly save time for model training and subsequent corpus distillation. This also helps avoid the issue of oversampling and thereby maintaining the simplicity of the method.

A fair comparison with the same size (133k) of helping corpora confirmed that sharing at least one of source and target languages tends to improve the final translation quality in cross-lingual TL settings. For instance, Hi→En has a better impact than En→Hi on Vi→En. Similarly, En→Hi leads to higher BLEU score than Hi→En for En→Vi.

5.1.4 Size vs. Speed vs. Translation Quality

Table 5 compares size, decoding time, and BLEU score for various models. As the model size drops with fewer layers and smaller hidden sizes, BLEU score also drops. However, the decoding time decreases significantly. Note that reducing the number of layers mainly impacts on the decoding time, whereas reducing hidden sizes does not have such a huge impact, as reported in Kim and Rush (2016).

We observed that the model with $L = 3$ and $H = 512$ are approximately 1.7 times (or 40%) smaller and 1.7 times (40%) faster than the 6-layer models despite exhibiting improved translation quality of 3.6 BLEU points in average. If one wishes to save decoding time, we suggest to train a model with $L = 1$ and $H = 512$, which is approximately 3.0 times smaller and 3.2 times faster than a 6-layer model, while having comparable translation quality. If the priority is reducing model size, then using models with $L = 3$ and $H \in \{256, 128\}$ are 5.1 times to 14.2 times smaller, even though they do not benefit much from narrowing down H. The model with $L = 3$ and $H = 256$ is comparable to the one with $L = 1$ and $H = 512$ in terms of quality, but the latter is 1.7 times smaller than the former. We recommend experimenting with different model sizes before choosing the best one for the target application.

5.2 Using Both ELR and Helping Corpora

Table 6 gives the BLEU scores achieved by models trained on both ELR and helping corpora, where we compare the distilled ("Y") and non-distilled ("N") versions of corpora as well as the three types of training ("ft," "mxt," and "mxft").

5.2.1 Importance of Transfer Learning for Efficient Models

Comparing the results of using only ELR corpora against the results of TL without SD, TL already gives 1-layer models that are competitive, if not better than the 3-layer models trained on non-distilled ELR corpora and the 6-layer models trained on distilled ELR corpora. The 1-layer models are 1.9 and 3.2 times faster as well as approximately 1.8 and 3.0 times smaller than the 3- and 6-layer models, respectively (see Table 5). It is thus reasonable to avoid SD altogether when time is of the essence.

Among the training methods, "mxft" was in most cases slightly better than "ft" and both of them are substantially better than "mxt." This highlights the importance of stage-wise TL rather than innocently training on a combination of all corpora. Note that "mxt" achieved the highest BLEU score for some configurations, and it should be a reasonable option when there is not enough time for stage-wise training.

5.2.2 Importance of Distillation with Transfer Learning for NMT Efficiency

Using at least one distilled corpus, either ELR or helping corpora, is important in improving the translation quality of compact models. For instance,

ELR	HD	TT	Vi→En								Hi→En							
			$L=1$		$L=2$		$L=3$		$L=6$		$L=1$		$L=2$		$L=3$		$L=6$

Table 6: BLEU scores for Vi→En and Hi→En translation tasks with greedy (G) and beam search (B). Models trained on either distilled ("Y") or non-distilled ("N") version of ELR and helping corpora ("ELR" and "HD" columns, respectively) using different domain adaptation techniques ("TT" column), are compared. The highest score(s) in each column are marked in bold.

the BLEU score of greedy search with the 1-layer models trained on some distilled data are up to 3.7 BLEU points higher than the best scores achieved by 1-layer models that do not use distilled data at all (21.5 and 19.9 for Vi→En and Hi→En by "N–N" models in Table 6, respectively). Although the gap between the performances tends to be narrower when the number of layers increases, this sacrifices compactness and decoding speed.

The behavior of models trained on distilled data differs depending on the combination of ELR and helping corpora. For Vi→En, distilling the ELR corpus ("Y–N") is more useful than distilling the helping corpus ("N–Y"). In contrast, for Hi→En, distilling the helping corpus ("N–Y") matters more. Recall that the Vi→En helping corpus is around 10 times smaller than the Hi→En helping corpus. This means that a compact model has to bear the burden of learning a much larger amount of knowledge from the larger helping corpus. Consequently, the compact model should be better at learning the Vi→En helping corpus, especially in its distilled form. Furthermore, given that the distilled ELR corpus for Vi→En already improves translation quality compared to its non-distilled counterpart, it should also help improve translation quality when used it in combination with the helping corpus. This is indicated by the best result for Vi→En achieved by distilling both the ELR and helping corpora. For this direction, the 2-layer models trained on distilled data are either competitive with if not better than the 6-layer models. For Hi→En, given that the size of helping corpus is significantly larger, distilling it into compact models is harder due to lack of parameters. This is the most likely reason behind the relatively small improvement by distilled data. Although the impact of SD on TL on Hi→En is not as impressive as for Vi→En, we advise experimenting with SD rather than not.

6 Conclusion

In this paper, we have explored the combination of transfer learning (TL) and sequence distillation for obtaining compact and fast models in extremely low-resource (ELR) settings. Our experiments on four translation directions revealed that leveraging helping corpora help in distilling ELR corpora that help train compact models with 3.6 average BLEU points improvement in translation quality. Compact models trained on distilled ELR corpora are not only fast but also give better translations than larger models trained on non-distilled ELR corpora. We showed the effects of choosing appropriate training methods, using domain indicator tags, and managing corpora sizes on translation quality. Our cost-benefit analysis of model size, decoding speed, and translation quality showed that we can achieve translation quality comparable to baselines trained on the original ELR corpora with models that are approximately 3.0 times smaller and 3.2 times faster than said baselines. We also showed that combining distilled ELR corpora with the distilled or non-distilled helping corpora, using simple TL methods, can further boost the performance of compact and hence fast NMT models. We strongly recommend to leverage distilled ELR

corpora through stage-wise TL for compact and high-quality NMT for ELR settings.

In our future work, we will extend our approach for a single compact multilingual NMT model, for instance, focusing on multi-parallel ALT dataset.

Abstract

Independence assumptions during sequence generation can speed up inference, but parallel generation of highly inter-dependent tokens comes at a cost in quality. Instead of assuming independence between neighbouring tokens (semi-autoregressive decoding, SA), we take inspiration from bidirectional sequence generation and introduce a decoder that generates target words from the left-to-right and right-to-left directions simultaneously. We show that we can easily convert a standard architecture for unidirectional decoding into a bidirectional decoder by simply interleaving the two directions and adapting the word positions and self-attention masks. Our interleaved bidirectional decoder (IBDecoder) retains the model simplicity and training efficiency of the standard Transformer, and on five machine translation tasks and two document summarization tasks, achieves a decoding speedup of ∼2× compared to autoregressive decoding with comparable quality. Notably, it outperforms left-to-right SA because the independence assumptions in IBDecoder are more felicitous. To achieve even higher speedups, we explore hybrid models where we either simultaneously predict multiple neighbouring tokens per direction, or perform multi-directional decoding by partitioning the target sequence. These methods achieve speedups to 4×–11× across different tasks at the cost of <1 BLEU or <0.5 ROUGE (on average).[1]

1 Introduction

Neural sequence generation aided by encoder-decoder models (Bahdanau et al., 2015; Vaswani et al., 2017) has achieved great success in recent years (Bojar et al., 2018; Song et al., 2019; Raffel et al., 2019; Karita et al., 2019), but still suffers from slow inference. One crucial bottleneck lies in its generative paradigm which factorizes the conditional probability along the target sequence $\mathbf{y} = \{y_1, y_2, \ldots, y_n\}$ of length n as follows:

$$p(\mathbf{y}|\mathbf{x}) = \prod_{t=1}^{n} p\left(y_t|\mathbf{y}_{<t}, \mathbf{x}\right), \quad (1)$$

where $\mathbf{x} = \{x_1, x_2, \ldots, x_m\}$ is the source sequence of length m. This factorization determines that target words can only be generated one-by-one in a sequential and unidirectional manner, which limits the decoding efficiency.

A promising direction to break this barrier is to generate multiple target words at one decoding step to improve the parallelization of inference (Gu et al., 2018; Stern et al., 2018). However, this introduces independence assumptions that hurt translation quality, since words produced in parallel are in fact likely to be inter-dependent. We hypothesize that there are groups of words that are less likely to be strongly inter-dependent than neighbouring words, which will allow for better parallelization. Inspired by bidirectional modeling (Zhang et al., 2019b, 2020), we resort to an alternative probabilistic factorization:

$$p^{\text{BD}}(\mathbf{y}|\mathbf{x}) = \prod_{t=1}^{\lceil n/2 \rceil} p\left(\overrightarrow{y_t}, \overleftarrow{y_{t'}}|\overrightarrow{\mathbf{y}_{<t}}, \overleftarrow{\mathbf{y}_{>t'}}, \mathbf{x}\right), \quad (2)$$

Introducing an independence assumption between t and $t' = n - t + 1$ allows for parallel word prediction from both the $\overrightarrow{\text{left-to-right}}$ and $\overleftarrow{\text{right-to-left}}$ directions. Based on this factorization, Zhou et al. (2019) propose synchronous bidirectional translation using a dedicated interactive decoder, and report quality improvements compared to left-to-right semi-autoregressive decoding (Wang et al., 2018, SA) in translation quality. However, their success comes along with extra computational overhead brought by the specialized decoder. Empirically, Zhou et al. (2019) only report a decoding

(a) IBDecoder, $h = 2, c = 1$ (b) SA, $h = 1, c = 2$ (c) Att. Mask for (1a, 1b)

(d) IMDecoder, $h = 4, c = 1$ (e) IBDecoder + SA, $h = 2, c = 2$ (f) Att. Mask for (1d, 1e)

Figure 1: Overview of the interleaved bidirectional decoder (IBDecoder, 1a), the semi-autoregressive decoder (SA, 1b), the interleaved multi-directional decoder (IMDecoder, 1d) and the bidirectional semi-autoregressive decoder (IBDecoder+ SA, 1e) on target sequence $\mathbf{y} = \{y_1, y_2, \ldots, y_6\}$. We reorganize the target sequence (purple), the word positions (green) and the self-attention mask (circles) to reuse the standard Transformer decoder. During inference, multiple target words are generated simultaneously at each step (dashed rectangles), improving the decoding speed. The self-attention masks are given in (1c) and (1f), where sold black circles indicate allowed attention positions. Red arrows indicate generation directions (h is the direction number), whose length denotes the number of words produced per direction (c). Blue rectangles denote words generated at the first step. The direction embedding (red rectangles) reflects the direction each target word belongs to. Apart from the left-to-right generation, IBDecoder jointly models the right-to-left counterpart within a single sequence. IMDecoder extends IBDecoder by splitting the sequence into several equal segments and performing bidirectional generation on each of them, while IBDecoder+SA allows each direction to produce multiple words.

speedup of 1.38×, slower than SA, although the factorization halves the decoding steps.

We combine the strengths of bidirectional modeling and SA, and propose interleaved bidirectional decoder (IBDecoder) for fast generation. As shown in Figure 1a, we interleave target words from the left-to-right and right-to-left directions and separate their positions to support reusing any standard unidirectional decoders, such as the Transformer decoder (Vaswani et al., 2017). We reorganize the self-attention mask to enable inter- and intra-direction interaction (Figure 1c) following SA. Unlike SA, we show through experiments that distant tokens from different directions are less inter-dependent, providing a guarantee for better performance. Compared to previous studies (Zhang et al., 2018d, 2019b, 2020; Zhou et al., 2019), our approach has no extra model parameters and brings in little overhead at training and decoding.

IBDecoder is speedup-bounded at 2×. To push this ceiling up, we explore strategies for multi-word simultaneous generation, including *multi-directional decoding* (IMDecoder, Figure 1d) and *SA* (Figure 1b). The former extends Eq. 2 by inserting more generation directions, while the latter allows each direction to produce multiple target words (Wang et al., 2018). These strategies offer us a chance to aggressively improve the decoding speed albeit at the risk of degenerated performance. To encourage multi-word generation in parallel, we propose a modified beam search algorithm.

We extensively experiment on five machine translation tasks and two document summarization tasks, with an in-depth analysis studying the impact of batch size, beam size and sequence length on the decoding speed. We close our analysis by examining the capacity of our model in handling long-range dependencies. On these tasks, IBDecoder yields ∼2× speedup against Transformer at inference, and reaches 4×–11× after pairing it with SA. Still, the overall generation quality is comparable. When we pair our method with sequence-level knowledge distillation (Kim and Rush, 2016), we outperform a Transformer baseline on 6 out of 7 tasks.

Our contributions are summarized below:

- We propose IBDecoder, following a bidirectional factorization of the conditional probability, for fast sequence generation. IBDecoder retains the training efficiency and is easy to implement.
- We extend IBDecoder to enable multi-word simultaneous generation by investigating integration with IMDecoder and SA. Results show that IBDecoder + SA performs better than IMDecoder.
- We propose a modified beam search algorithm to support step-wise parallel generation.
- On several sequence generation benchmarks, IBDecoder yields ∼2× speedup against Transformer at inference, and reaches 4×–11× af-

ter pairing it with SA. Still, the overall generation quality is comparable.

2 Related Work

Efforts on fast sequence generation come along with the rapid development of encoder-decoder models (Vaswani et al., 2017). A straightforward way is to reduce the amount of computation. Methods in this category range from teacher-student model (Kim and Rush, 2016; Hayashi et al., 2019), constrained softmax prediction (Hu et al., 2015), beam search cube pruning (Zhang et al., 2018c), float-point quantization (Wu et al., 2016; Bhandare et al., 2019), model pruning (See et al., 2016), to simplified decoder architectures, such as lightweight recurrent models (Zhang et al., 2018b; Zhang and Sennrich, 2019; Kim et al., 2019), average attention network (Zhang et al., 2018a), merged attention network (Zhang et al., 2019a), dynamic convolution (Wu et al., 2019), and hybrid attentions (Shazeer, 2019; Wang et al., 2019), .etc.

Nonetheless, the above methods still suffer from the inference bottleneck caused by the sequential nature of autoregressive models. Instead, Gu et al. (2018) propose non-autoregressive generation where target words are predicted independently, leading to great speedup, albeit at a high cost to generation quality. Follow-up studies often seek solutions to recover the performance (Libovický and Helcl, 2018; Guo et al., 2019; Shao et al., 2020; Ghazvininejad et al., 2020; Ran et al., 2020), but also reveal the trade-off between the quality and speed in terms of autoregressiveness. This motivates researchers to discover the optimal balance by resorting to semi-autoregressive modeling (Wang et al., 2018; Stern et al., 2018), iterative refinement (Lee et al., 2018; Stern et al., 2019; Ghazvininejad et al., 2019) or in-between (Kaiser et al., 2018; Akoury et al., 2019).

We hypothesize that generation order affects the felicity of independence assumptions made in semi-autoregressive modelling. Unlike generation with flexible orders (Emelianenko et al., 2019; Stern et al., 2019; Gu et al., 2019a), we employ deterministic generation order for model simplicity and training efficiency, specifically focusing on bidirectional decoding. The study of bidirectional modeling dates back to the era of phase-based statistical machine translation (Watanabe and Sumita, 2002; Finch and Sumita, 2009) and recently gained popularity in neural machine translation (Liu et al., 2016; Sennrich et al., 2016a; Zhang et al., 2019c,b; Zheng et al., 2019). Unfortunately, these methods either design complex neural decoders, which hurts training efficiency, and/or perform the left-to-right and right-to-left inference separately followed by rescoring, which slows down decoding. By contrast, our model speeds up inference while maintaining training speed.

Our work is closely related to SA (Wang et al., 2018) and synchronous bidirectional generation (Zhou et al., 2019). IBDecoder extends SA to incorporate information from different directions. In contrast to Zhou et al. (2019), we only make minimal changes to the standard Transformer decoder, which benefits efficiency during training and inference, and makes our method easy to implement. We also find improvements in both decoding speed and translation quality compared to (Wang et al., 2018; Zhou et al., 2019).

3 Autoregressive Transformer

Transformer (Vaswani et al., 2017), the state-of-the-art neural sequence generation model, follows the autoregressive factorization as in Eq. 1. To handle the dependency of target word y_t on previous target words $\mathbf{y}_{<t}$, Transformer relies on a masked self-attention network in the decoder:

$$\textsc{Att}(\mathbf{Y}^l, \mathbf{M}) = f\left(\frac{\mathbf{Q}^l {\mathbf{K}^l}^T}{\sqrt{d}} + \mathbf{M}\right)\mathbf{V}^l \quad (3)$$

where $\mathbf{Q}^l, \mathbf{K}^l, \mathbf{V}^l = \mathbf{W}_q^l\mathbf{Y}^l, \mathbf{W}_k^l\mathbf{Y}^l, \mathbf{W}_v^l\mathbf{Y}^l \in \mathbb{R}^{n\times d}$, $f(\cdot)$ denotes softmax operation, d is model dimension and l is layer depth. $\mathbf{W}_q, \mathbf{W}_k, \mathbf{W}_v \in \mathbb{R}^{d\times d}$ are trainable parameters.

The mask matrix $\mathbf{M} \in \mathbb{R}^{n\times n}$ limits the access of attention to only the past target words. Formally, given the target sequence length n, this matrix can be constructed by the following masking function:

$$\mathcal{M}_{i,j}(h,c) = \begin{cases} 0, & \text{if } \lceil i/(h\cdot c)\rceil \geq \lceil j/(h\cdot c)\rceil \\ -\infty, & \text{otherwise} \end{cases} . \quad (4)$$

where $0 < i, j < n$, h denotes the number of generation directions, and c is the number of target words predicted per direction. By default, the Transformer decoder is unidirectional and generates words one-by-one. Thus, $\mathbf{M} = \mathcal{M}(1,1)$. The infinity here forces softmax output a probability of 0, disabling invalid attentions.

The input layer to Transformer's decoder is the addition of target word embedding $\mathbf{E}_\mathbf{y}$ and word

position encoding $\text{PE}_{\mathcal{T}}$, i.e $\mathbf{Y}^0 = \mathbf{E}_{\mathbf{y}} + \text{PE}_{\mathcal{T}} \in \mathbb{R}^{n \times d}$. $\mathcal{T}$ maps $\mathbf{y}$ to its word position sequence, which is a simple indexing function (Figure 1b):

$$\mathcal{T}_t = t - 1, \tag{5}$$

where $t = 1 \dots n$. Transformer adopts the sinusoidal positional encoding to project these indexes to real-space embeddings, and uses the last-layer decoder output $\mathbf{Y}^L$ to predict the respective next target word. We explain how to accelerate generation by reordering $\mathbf{y}$, adjusting h, c and $\mathcal{T}$ next.

4 Interleaved Bidirectional Decoder

The structure of Transformer is highly parallelizable, but the autoregressive schema $(h = 1, c = 1)$ blocks this parallelization during inference. We alleviate this barrier by exploring the alternative probabilistic factorization in Eq. 2 to allow words predicted from different directions simultaneously.

We propose IBDecoder as shown in Figure 1a. We reuse the standard decoder's architecture in a bid to largely inherit Transformer's parallelization and avoid extra computation or parameters, rather than devising dedicated decoder architectures (Zhou et al., 2019; Zhang et al., 2020). To make the left-to-right and right-to-left generation collaborative, we reorganize the target sequence and the word positions below (purple and green rectangles in Figure 1a):

$$\mathbf{y}^{\text{BD}} = \left[y_1 y_n, y_2 y_{n-1}, ..., y_{\lfloor n/2 \rfloor + 1}\right], \tag{6}$$

$$\mathcal{T}_t^{\text{BD}} = (-1)^{(t-1)} \lceil t/2 \rceil. \tag{7}$$

By following the generation order defined by Eq. 2, the sequence $\mathbf{y}^{\text{BD}}$ interleaves $\mathbf{y}_{1:\lfloor n/2 \rfloor}$ and $\mathbf{y}_{\lfloor n/2 \rfloor + 1:n}$ and converts a bidirectional generation problem to a unidirectional one. We introduce negative positions to $\mathcal{T}^{\text{BD}}$ to retain the locality bias of sinusoidal positional encodings in $\mathbf{y}^{\text{BD}}$.[2] Compared to $(\mathbf{y}, \mathcal{T})$, the reorganized sequences $(\mathbf{y}^{\text{BD}}, \mathcal{T}^{\text{BD}})$ have the same length, thus with no extra overhead.

We also adapt the self-attention mask to permit step-wise bidirectional generation:

$$\mathbf{M}^{\text{BD}} = \mathcal{M}(2, 1), \tag{8}$$

where IBDecoder has $h = 2$ generation directions. This corresponds to the relaxed causal mask by Wang et al. (2018), which ensures access to all predictions made in previous time steps[3] and allows for interactions among the tokens to be produced per time step. Although two words are predicted independently at each step, the adapted self-attention mask makes their corresponding decoding context complete; each word has full access to its corresponding decoding history, i.e. the left-to-right ($\mathbf{y}_{1:t}$) and right-to-left ($\mathbf{y}_{n-t+1:n}$) context. Except for $(\mathbf{y}^{\text{BD}}, \mathbf{M}^{\text{BD}}, \mathcal{T}^{\text{BD}})$, other components in Transformer are kept intact, including training objective.

4.1 Beyond Two-Word Generation

Eq. 2 only supports two-word generation, which indicates an upper bound of 2× speedup at inference. To improve this bound, we study strategies for multi-word generation. We explore two of them.

Multi-Directional Decoding Similar to IBDecoder, IMDecoder also permutes the target sequence. It inserts multiple generation directions (i.e. increases h), with each direction producing one word per step (i.e. $c = 1$). As shown in Figure 1d, it splits the target sequence into several roughly equal segments followed by applying IBDecoder to each segment (thus an even h required). Formally, IMDecoder reframes the target sequence and word positions as follows:

$$\mathbf{y}^{\text{MD}} = \left[\mathbf{y}_{1,k}^{\text{BD}}, \mathbf{y}_{2,k}^{\text{BD}}, \dots, \mathbf{y}_{h/2,k}^{\text{BD}}\right]_{k=1}^{\lceil n/h \rceil}, \tag{9}$$

$$\mathcal{T}_t^{\text{MD}} = \left(\lfloor {}^{t-1}/_{h} \rfloor, t - 1 \bmod h\right), \tag{10}$$

where $\mathbf{y}_{i,k}^{\text{BD}}$ denotes the k-th word of $\mathbf{y}_i^{\text{BD}}$, which is the i-th segment of $\mathbf{y}$ reordered by IBDecoder(${}^{h}/_{2}$ segments in total). $\mathcal{T}^{\text{MD}}$ decomposes the word position into two parts. The first one represents the index of decoding step where each word is predicted; the second one denotes the generation direction each target word belongs to. Specifically, we record the corresponding direction indices and add a group of trainable direction embeddings (red rectangles in Figure 1d) into the decoder input. IMDecoder uses the following self-attention mask:

$$\mathbf{M}^{\text{MD}} = \mathcal{M}(h, 1) \tag{11}$$

Semi-Autoregressive Decoding Instead of partitioning the target sequence, another option is to produce multiple target words per direction at each

[2] Consider Figure 1a. We cannot reorder position encodings along with embeddings (1,6,2,5,...) because we do not know sentence length at test time. Simply using vanilla position encodings (1,2,3,4,...) would increase the embedding distance between positions within a direction.

[3] Note that with two tokens produced per time step, decoder inputs are shifted by two.

20: **return** sort $(post(h_t), s_t) \in \mathcal{H}_{finish}$ by $\frac{s_t}{t}$

step (i.e. increase c, Wang et al., 2018). SA assumes that neighbouring words are conditionally independent, despite the fact that tokens in natural language are typically highly inter-dependent.

We combine SA with IBDecoder (Figure 1e) with the expectation that producing 2 neighbouring tokens independently per direction is less harmful than producing 4 neighbouring words in parallel. We reuse the sequence $\mathbf{y}^{\text{BD}}$ and $\mathcal{T}^{\text{BD}}(n)$ for the decoder input, but enlarge the attention range in the self-attention mask to assist multi-word generation (Figure 1f):

$$\mathbf{M}^{\text{SA}} = \mathcal{M}(2, c). \tag{12}$$

4.2 Inference

To handle multiple predicted words per decoding step simultaneously, we adjust the beam search algorithm as in Algorithm 1. For each partial hypothesis h_t, we predict $z = h \cdot c$ words in parallel. We thus first extract the B top-scoring predictions $\mathbf{W}_p$ of probability $\mathbf{P}$ for all z positions (line 6), followed by pruning the resulting search space of size $\mathcal{O}(B^z)$ through an outer-addition operation to size B (line 7). The scores $\mathbf{s} \in \mathbb{R}^B$ (line 7) and the backtraced words $\mathbf{W} \in \mathbb{R}^{B \times z}$ (line 8) are then used for normal decoding. Note that each complete hypothesis requires a simple deterministic post-processing to recover its original word order (line 20). In contrast to Zhou et al. (2019), we do not separate the left-to-right beam from the right-to-left beam.

End-of-Hypothesis Condition With multiple predicted target words, determining whether one hypothesis is complete or not becomes challenging. We adopt a simple strategy: one hypothesis is assumed complete once any word in the predictions hits the end-of-sentence symbol ("[/s]") (line 10). We leave the study of alternatives for the future.

5 Experiments

Setup We test our model on machine translation (MT) and document summarization. We train MT models on five different language pairs: WMT14 English-German (En-De, Bojar et al., 2014), WMT14 English-French (En-Fr, Bojar et al., 2014), WMT16 Romanian-English (Ro-En, Bojar et al., 2016), WMT18 English-Russian (En-Ru, Bojar et al., 2018) and WAT17 Small-NMT English-Japanese (En-Ja, Nakazawa et al., 2017). Translation quality is measured by BLEU (Papineni et al., 2002), and we report detokenized BLEU using the toolkit *sacreBLEU* (Post, 2018)[4] except for En-Ja. Following Gu et al. (2019b), we segment Japanese text with KyTea[5] and compute tokenized BLEU. We train document summarization models on two benchmark datasets: the non-anonymized version of the CNN/Daily Mail dataset (CDMail, Hermann et al., 2015) and the Annotated English Gigaword (Gigaword, Rush et al., 2015). We evaluate the summarization quality using ROUGE-L (Lin, 2004).

We provide details of data preprocessing and model settings in Appendix A. We perform thorough analysis of our model on WMT14 En-De. We also report results improved by knowledge distillation (KD, Kim and Rush, 2016).

Table 1: Performance on WMT14 En-De for different models with respect to beam size (B), generation direction number (h, Eq. 4) and predicted token number per step (c, Eq. 4). *BLEU*: detokenized BLEU for models trained from scratch, *+KD*: detokenized BLEU for models trained with knowledge distillation. *Latency* (in millisecond) and *Speedup* are evaluated by decoding the test set with a batch size of 1, averaged over three runs. We report the latency and speedup for ②, ③ and ④ trained with KD. *Train* compares the training speed averaged over 100 steps. Time is measured on GeForce GTX 1080.

5.1 Results on WMT14 En-De

Table 1 compares the performance of our models on WMT14 En-De. Relaxing the autoregressiveness with IBDecoder yields slightly worse translation quality compared to Transformer (-0.7 BLEU, ①→②, w/o KD, $B = 4$). Unlike Zhang et al. (2020), we observe no quality improvement, but our model delivers a speedup of 1.90×∼2.33× at inference, clearly surpassing the simple greedy decoding baseline (1.32×) and BIFT (0.89×) (Zhang et al., 2020). The dropped quality is easily recovered with knowledge distillation (+0.2 BLEU, ①→②, w/ KD, $B = 4$).

Going beyond two-word generation, which enhances independence, greatly decreases the performance (②→③,④, w/o KD) while enlarging the speedup to 3.3×–4.5×. Compared to SA, the quality degradation with IMDecoder is larger, both w/ and w/o KD. We ascribe this to the difficulty of structure planning, as IMDecoder has to guess words in the middle of the sequence at the start of generation. We employ SA for the following experiments.

In contrast to existing work (Zhang et al., 2018d, 2019b, 2020; Zhou et al., 2019), our models marginally affect the training efficiency (0.98× vs 0.61× (Zhang et al., 2020)), and require no extra linguistic information (Akoury et al., 2019). Our results also suggest that the degree each model benefits from KD varies. Follow-up studies should report performance w/ and w/o KD.

Ablation Study We carry out an ablation study as shown in Table 2. Replacing the attention mask with the vanilla one (①→②) introduces unnecessary independence assumptions and reduces performance by 0.5 BLEU. Using vanilla positional encodings (③) also reduces performance -0.3 BLEU, indicating that we benefit from preserving the locality bias of sinusoidal encodings within each direction. Changing the generation direction from the side-to-middle (①) to the middle-to-side (④) dramatically increases the learning difficulty (-5.5 BLEU).

ID	Model	h	c	BLEU↑
1	IBDecoder	2	1	26.2
2	1 + vanilla mask	2	1	25.7
3	1 + vanilla positions	2	1	25.9
4	1 + middle-to-side	2	1	20.7
5	1 + indep. directions	2	1	23.9
6	vanilla SA	1	2	24.1
7	1 + SA	2	2	23.0
8	vanilla SA	1	4	18.7

Table 2: Ablation study on WMT14 En-De. Beam size 4. All models are trained from scratch. *vanilla mask*/*vanilla positions*: the self-attention mask ($\mathcal{M}(1, 1)$, Eq. 4) and word positions ($\mathcal{T}$, Eq. 5) used in Transformer. *middle-to-side*: generate words from the middle of the sequence to its two ends, a reverse mode of IBDecoder. *indep. directions*: disable cross-direction interaction. *vanilla SA*: predict multiple target words per step following one direction (Wang et al., 2018).

In IBDecoder, the two translation directions are interlinked, i.e. predictions are conditioned on the history of both directions. We can remove cross-direction attention, essentially forcing the model to produce the left and right half of sequences independently. Such an independent generation performs poorly (-2.3 BLEU, ①→⑤), which supports the importance of using bidirectional context and resonates with the finding of Zhou et al. (2019).

Vanilla SA vs. IBDecoder Our IBDecoder shares architectural properties with vanilla SA (Wang et al., 2018), namely the independent generation of two tokens per time step, and the

	Left-to-Right	Bidirectional
Autoregressive	4.04	4.86
Semi-Autoregressive	6.95	4.72
Estimated PMI	0.235	-0.014

Table 3: Perplexity of autoregressive and semi-autoregressive models with different factorizations, and estimated average point-wise mutual information between words that are predicted independently. Measured on WMT14 En-De test set. *Left-to-Right*: $h = 1$, *Bidirectional*: $h = 2$; Autoregressive: $z = 1$, Semi-autoregressive: $z = 2$. The estimated PMI shows that the inter-dependence of word pairs predicted in parallel by vanilla SA is stronger than for those predicted simultaneously by IBDecoder.

Model	$L/h/c$	BLEU↑	Speedup↑
Transformer	6/1/1	26.9	1.00×
+ student	2/1/1	26.0	2.19×
+ KD	2/1/1	26.7	2.32×
IBDecoder	6/2/1	26.2	1.90×
+ student	2/2/1	25.0	4.29×
+ KD	2/2/1	26.6	4.41×
IBDecoder + SA	6/2/2	23.0	3.31×
+ student	2/2/2	21.5	7.13×
+ KD	2/2/2	24.5	7.24×

Table 4: Detokenized BLEU and decoding speedup for student models on WMT14 En-De with reduced decoder depth L (encoder depth remains constant). Beam size 4.

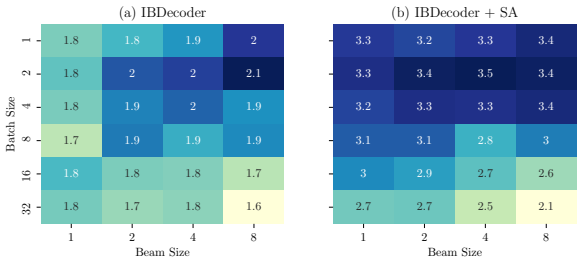

Figure 2: Speedup against Transformer vs. batch size and beam size on WMT14 En-De. Comparison is conducted under the same batch size and beam size. IBDecoder (+SA) is trained with KD. Our model consistently accelerates decoding.

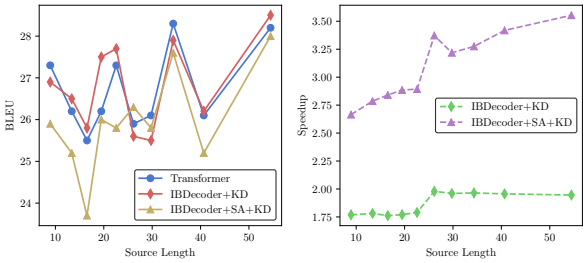

Figure 3: BLEU (solid lines, left) and speedup (dashed lines, right) as a function of source sentence length on WMT14 En-De. We sort the test set according to the source sentence length and uniformly divide it into 10 bins (274 sentences each). IBDecoder (+SA) is trained with KD. Beam size 4.

adapted self-attention mask, but crucially differ in their generation order and independence assumptions, with vanilla SA operating from left-to-right, and IBDecoder interleaving left-to-right and right-to-left decoding.

Our ablation results in Table 2 show that IBDecoder substantially outperforms vanilla SA (2.1/4.3 BLEU, ①→⑥/⑦→⑧). To further investigate the difference in independence assumptions between the two approaches, we compare estimated point-wise mutual information (PMI) of the words being predicted independently by IBDecoder and vanilla SA.[6] Results in Table 3 show that the PMI in IBDecoder (-0.014) is significantly smaller than that in vanilla SA (0.235), supporting our assumption that distant words are less inter-dependent on average. This also explains the smaller quality loss in IBDecoder compared to vanilla SA.

On Teacher-Student Model One classical approach to improving decoding efficiency is training a small student model w/ KD. Results in Table 4 support this: Transformer with a student model produces similar performance w/ KD but runs 2.32× faster, even better than IBDecoder (1.90×). Combining the student schema with IBDecoder increases the speedup to 4.41× without hurting the performance (26.6 BLEU, w/ KD). In exchange of 2.4 BLEU, we could reach 7.24× faster decoding with SA. The compatibility of our model with the teacher-student framework reflects the generalization of our bidirectional modeling. The results also demonstrate that efficiency improvements from faster autoregressive decoding, here obtained by reducing the number of decoder layers L[7], and from bidirectional decoding, are orthogonal.

Impact of Batch and Beam Size Figure 2 shows speedups over a standard Transformer with varying batch and beam sizes. When batch size < 8, increasing beam size improves the speedup; while the impact becomes negative with batch size ≥ 8. Overall, our model is consistently faster than Transformer at inference, regardless of the batch and beam size.

Impact of Source Sentence Length Although translation quality fluctuates over the source sentence length, Figure 3 shows that our model shares the same performance pattern with the baseline.

[6]Details about PMI estimation are given in Appendix B

[7]Also note the concurrent work by (Kasai et al., 2020).

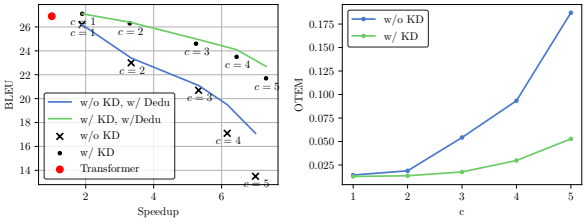

Figure 4: BLEU versus speedup (left) and OTEM (right) for different c on WMT14 En-De. Generation directions: $h = 2$. Beam size 4. OTEM↓: a metric measuring the degree of over-translation (Yang et al., 2018). Larger c indicates more independence between neighbouring tokens and results in more severe over-translation. Deduplication (Dedu) improves translation quality for large c.

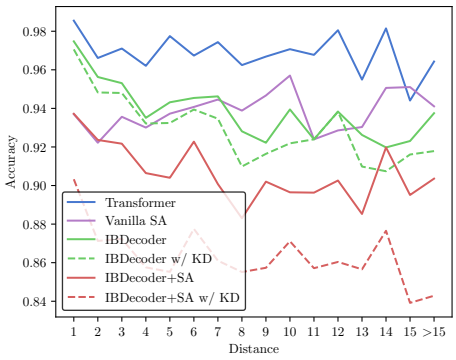

Figure 5: Accuracy of different models over distances on the subject-verb agreement task in *Lingeval97*.

With respect to the speedup, our model performs better when translating longer source sentences.

Effect of c Results in Figure 4 show that c controls the trade-off between translation quality and speedup. With larger c, more target tokens are predicted per decoding direction, leading to better speedup, but causing a larger performance drop w/ and w/o KD. Further analysis reveals that, as the dependency between predicted target words weakens, our model suffers from more serious over-translation issue, yielding larger OTEM (Yang et al., 2018). Although n-gram deduplication slightly improves quality[8], it does not explain the whole performance drop, echoing with Wang et al. (2018). We recommend using $c = 2$ for a good balance. In addition, the reduction of OTEM by KD in Figure 4 partially clarifies its improvement on quality.

Analysis on Long-range Dependency We adopt the subject-verb agreement task from *Lingeval97* (Sennrich, 2017) for analysis. We can see from the results in Figure 5 that IBDecoder performs similarly to the original Transformer for agreement over short distances, but agreement over longer distances drops on average. In contrast, models that include SA show steep drops in accuracy for short distances.

Curiously, KD seems to harm agreement scores even though it led to higher BLEU. Overall, these results suggest that BLEU does not show the full quality loss incurred by our independence assumptions. This deficiency also provides evidence for the performance drop in Figure 4.

[8] we only applied deduplication for results in Figure 4.

Table 5: Comparison to several recent fast sequence generation models on WMT14 En-De. *: trained w/ KD. †: tokenized BLEU. ◇: deduplication applied. *SU*: short for speedup.

Comparison to Previous Work Results in Table 5 show that our model outperforms SynST (Akoury et al., 2019) in quality, and slightly surpasses the Levenshtein Transformer (Gu et al., 2019b) in speed. Particularly, our model ($27.50^{\dagger}/2.33\times$) surpasses SAT (Wang et al., 2018) ($26.09^{\dagger}/2.07\times$) and SBSG (Zhou et al., 2019) ($27.22^{\dagger}/1.61\times$) in terms of both quality and speed. Our model doesn't heavily rely on extra linguistic knowledge (Akoury et al., 2019), neither requires complex pseudo training data construction (Gu et al., 2019b). Compared to these prior studies, our approach is simple but effective.

5.2 Results on Other Tasks

Table 6 shows MT results for other translation directions, and for document summarization. Regardless of syntactic, morphological, transcript and sequence-length differences, our model achieves comparable generation quality and 1.75×–11.15× speedup over different tasks. With KD, our model even outperforms the Transformer baseline on 5 out of 6 tasks. In particular, our model succeeds on the

Table 6: Generation quality (BLEU for MT, Rouge-L for summarization) and latency(ms)/speedup on different tasks. We compare IBDecoder (+SA) with Transformer. Best quality is in **bold**.

CDMail task which previous non-autoregressive models rarely attempt due to its lengthy target sequence, although our model suffers from the long-range dependency issue as in Figure 5.

6 Conclusion and Future Work

We present interleaved bidirectional sequence generation to accelerate decoding by enabling generation from the left-to-right and right-to-left directions simultaneously. We combine the strengths of SBSG (Zhou et al., 2019) and SA (Wang et al., 2018), and propose a simple interleaved bidirectional decoder (IBDecoder) that can be easily implemented on top of a standard unidirectional decoder, like Transformer, via interleaving the target sequence and tweaking the word positions and self-attention masks. IBDecoder inherits Transformer's training parallelization with no additional model parameters, and is extensible with SA and multi-directional decoding. We show that the independence assumptions we introduce between the two directions are less harmful to translation quality than the independence assumptions in left-to-right SA. On a series of generation tasks, we report comparable quality with significant inference speedup (4×–11×) and little training overhead. We also show that the approach is orthogonal to speedups to autoregressive decoding, e.g. by reducing model size.

In the future, we would like to further improve multi-directional generation, and will investigate alternative ways to partition the target sequence and encode positional information. We are also interested in better measuring and reducing the quality loss resulting from long-distance dependencies. Finally, we would like to adapt our interleaving approach to other sequence-to-sequence architectures.
